ONE-HUNDRED-AND-SIXTY-FOURTH SESSION, 1917-1918.

SESSIONAL ARRANGEMENTS.

The Opening Meeting of the One Hundred and Sixty-Fourth Session was held on Wednesday, November 21st, when an address was delivered by ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, on "Science and its Functions." (See pp. 6-19, below.) The chair was taken at 4.30 p.m.

PAPERS TO BE READ BEFORE CHRISTMAS.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

NOVEMBER 28.—COLONEL MERVYN O'GORMAN, C.B., "Aerial Transport after the War."

DECEMBER 5.—SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., "Discovery and Invention" (Inaugural "Trueman Wood" Lecture). ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the Chair.

12.—LORD CHARNWOOD, "Technical Training for Disabled Soldiers and Sailors."

19.—PROFESSOR J. WEMYSS ANDERSON, M.Inst.C.E., M.I.Mech.E., Dean of the Faculty of Engineering and Lecturer in Refrigeration, University of Liverpool, "The Cold Storage Industry." THE HON. SIR THOMAS MACKENZIE, K.C.M.G., in the Chair.

COLONIAL SECTION.

Monday afternoon, at 4.30 p.m.:—

NOVEMBER 26. LIEUT.-COLONEL THE HON. SIR JOHN McCALL, M.D., LL.D., Agent-General for Tasmania, "Land Settlement within the Empire." THE RIGHT HON. WALTER H. LONG, LL.D., M.P., F.R.S., Secretary of State for the Colonies, in the Chair.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

DECEMBER 13. D. T. CHADWICK, I.C.S., "The Trade of India with Russia, France, and Italy." THE RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, in the Chair.

PAPERS TO BE READ AFTER CHRISTMAS.

LORD LEVERHULME, "The Relations between Capital and Labour—Reasonable Hours, Co-partnership, and Efficiency."

SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Commercial Intelligence Department, "The Organisation of Commercial Intelligence." THE RIGHT HON. LORD FARINGDON in the Chair.

ALEXANDER NEWLANDS, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in the British Isles."

FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., in the Chair.

MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." SIR ASTON WEBB, K.C.V.O., C.B., R.A., in the Chair.

WILLIAM FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of the Mineral Resources of the Empire." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., in the Chair.

ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

H. M. SURTEES TUCKWELL, M.I.Mech.E., "The Tata Iron and Steel Works" (India).

SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India."

SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana."

C. DU P. CHIAPPINI, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

The following series of papers has also been arranged, dealing with the Application of Scientific Research to the development of particular British Industries:—

REGINALD S. CLAY, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry."

GEORGE MARTINEAU, C.B., "The Sugar Industry."

JOHN B. FARMER, D.Sc., M.A., F.R.S., F.L.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber-Planting Industry."

W. LAWRENCE BALL, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

SIR WILLIAM GEORGE WATSON, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." SIR ARTHUR D. STEEL-MAITLAND, Bt., M.P., in the Chair.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

January 17, February 14, March 14, April 18, May 30.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 5, March 5, April 30.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced) :—

H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, "Progress in the Metallurgy of Copper." Three Lectures.

December 3, 10, 17.

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

January 21, 28, February 4, at 8 p.m.

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: the Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22, at 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13 and 14, at 4.30 p.m.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m. :—

P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage." Two Lectures.

January 2, 9.

PROCEEDINGS OF THE SOCIETY.

THE SOCIETY was founded in 1754, and incorporated by Royal Charter in 1847, for "The Encouragement of the Arts, Manufactures, and Commerce of the Country, by bestowing rewards for such productions, inventions, or improvements as tend to the employment of the poor, to the increase of trade, and to the riches and honour of the kingdom: and for meritorious works in the various departments of the Fine Arts; for Discoveries, Inventions, and Improvements in Agriculture, Chemistry, Mechanics, Manufactures, and other useful Arts; for the application of such natural and artificial products, whether of Home, Colonial, or Foreign growth and manufacture, as may appear likely to afford fresh objects of industry, and to increase the trade of the realm by extending the sphere of British commerce; and generally to assist in the advancement, development, and practical application of every department of science in connection with the Arts, Manufactures, and Commerce of this country." In 1908 the Society was granted the privilege of adding "Royal" to its title.

Fellowship.—At the Annual General Meeting held on June 24th, 1914, a By-Law was made authorising all Members of the Society to use the designation of Fellow.

Ordinary Meetings.—Meetings are held every Wednesday during the Session, at which papers on subjects relating to inventions, improvements, discoveries, and other matters connected with Arts, Manufactures, and Commerce are read and discussed.

Indian Section.—This Section was established in 1869, for the discussion of subjects connected with our Indian Empire. Six or more Meetings are held during the Session.

Colonial Section.—This Section was formed in 1874 under the title of the African Section. It was enlarged in 1879, to include the consideration of subjects connected with the Colonies and Dependencies. Four or more Meetings are held during the Session.

Cantor Lectures.—These Lectures originated in 1863, with a bequest by Dr. Cantor. The Lectures deal with the latest applications of Science and Art to practical purposes, and are, as far as possible, experimentally illustrated.

Fothergill Lectures.—Courses of Lectures, similar to the Cantor Lectures, are given from time to time under this bequest.

Howard Lectures.—The bequest of Mr. Thomas Howard (1872) is now devoted to occasional courses of Lectures on motive power and its applications.

Shaw Lectures.—Under the Shaw bequest Lectures on Industrial Hygiene are given from time to time.

Aldred Lecture.—The bequest of the late Dr. Aldred has been devoted to the establishment of an Annual Lecture.

Cobb Lectures.—Funds have been provided for occasional Lectures in memory of the late Mr. Francis Cobb.

Juvenile Lectures.—A Short Course of Lectures, suited for a Juvenile audience, is delivered to the children of Fellows during the Christmas holidays.

Admission to Meetings. — Fellows have the right of attending the above Meetings and Lectures. They require no tickets, but are admitted on signing their names. Every Fellow can admit two friends to the Ordinary and Sectional Meetings, and to the Cantor and other Lectures. Books of tickets for the purpose are supplied, but admission can also be obtained on the personal introduction of a Fellow. For the Juvenile Lectures special tickets are issued

Journal of the Royal Society of Arts.—The *Journal*, which is sent free to Fellows, is published weekly, and contains full Reports of all the Society's Proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce.

Examinations.—Examinations, founded in 1854, are held annually by the Society, through the agency of Local Committees, at various centres in the country. They are open to any person. The subjects include the principal elements of Commercial Education and Music. Full particulars of the Examinations can be had on application to the Secretary.

Library and Reading-room.—The Library and Reading-room are open to Fellows, who are also entitled to borrow books.

A History of the Society, written by Sir Henry Trueman Wood, Secretary of the Society from 1879 to 1917, has lately been published (John Murray, pp. 558, 15*s*. net), and can be obtained from any bookseller. It gives a history of the Society's work from 1754 to 1880.

Conversazioni are held, to which Fellows are invited, each Fellow receiving a card for himself and a lady.

Election of Fellows.—Candidates are proposed by Three Fellows, one of whom, at least, must sign on personal knowledge; or are nominated by the Council.

The Annual Subscription is Two Guineas, payable in advance, and dates from the quarter-day preceding election; or a Life Subscription of Twenty Guineas may be paid. There is no Entrance Fee.

CALENDAR FOR THE SESSION.

The following is the Calendar for the Session 1917–1918. It is issued subject to any necessary alterations :—

The Cantor Lectures, the Ordinary Meetings, and the Meetings of the Indian Section and the Colonial Section will be held (unless otherwise announced) at Half-past Four o'clock.

The Annual General Meeting will be held at Four o'clock.

The Juvenile Lectures will be given at Three o'clock.

PROCEEDINGS OF THE SOCIETY.

FIRST ORDINARY MEETING.

Wednesday, November 21st, 1917; ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Aplin, William, Assoc.Inst.M.M., Technical College, Mount Morgan, Queensland, Australia.

Armstrong, Ernest, Linton House, Haydon Bridge, Northumberland.

Banatvala, Curtsetji Jamsetji, B.A., Mount villas, Bandra, Bombay, India.

Bayley, Victor, C.I.E., Assoc.M.Inst.C.E., care of Railway Board, Simla, India.

Bhándare, Rao Bahadur S.T., Inspector-General of State Records, Lashkar, Gwalior, Central India.

Blair, Lieut. John Hamilton, R.N., D.S.O., H.M.S. "Titania," Submarine Depôt, care of G.P.O., London.

Clowes, William Archibald, Berwyn, St. Mary's road, Ditton Hill, Surrey.

Collier, Harry Samuel, The Orchard, Buckland, near Betchworth, Surrey.

Cox, W. Howard, Union Central Life Insurance Co., 1107, Union Central Building, Cincinnati, Ohio, U.S.A.

D'Abreu, Aubyn Reginald, 3rd Divisional Signal Company, Royal Engineers, Mesopotamia Expeditionary Force.

Dhruva, Maganlal Dhaneshwar, Nandod, Rajpipla State, Rewakantha, India.

Gwyther, Harry Earlston, M.Inst.C.E., The Leopoldina Railway Company, Caixa 291, Rio de Janeiro, Brazil.

Hamshaw, William Hamlin, J.P., 61, York mansions, Battersea Park, S.W. 11.

Hancock, Walter Charles, 10, Upper Chadwell street, Myddelton square, E.C. 1.

Hay, Leslie, Messrs. Finlay & Co., Ltd., Calcutta, India.

Henriques, Elias Cosmas, A.R.I.B.A., Culvem, District Thana, Bombay, India.

Hutchinson, C. M., B.A., Imperial Department of Agriculture, Pusa, India.

Jack, Robert Ernest, I.C.S., United Service Club, Calcutta, India.

Jennings, Frederick W., Messrs. Ashwell & Nesbit, Ltd., 12, Great James street, Bedford row, W.C. 1.

Johnson, Arthur Laurence, M.A., Southcote, Cambridge road, Middlesbrough.

Johnson, Harold, Macmillan building, 276, Hornby road, Bombay, India.

Jones, F. J. Clinch, 20, Longley lane, Northenden, Cheshire.

Jordan, Frank, 34, Trafalgar place, Brynmill, Swansea.

Kemp, Walter Lowther, Messrs. Barker & Co., Singapore, Straits Settlements.

Krishnagar, Maharaja of (Kshaunish Chandra Roy Bahadur), The Palace, Krishnagar, District Nadia, Bengal, India.

Kroll, Clifton H., 311, California street, San Francisco, California, U.S.A.

Laird, James, 13, Berlin road, Catford, S.E. 6.

Lang, Rev. George, Anniston, Alabama, U.S.A.

Locker, Thomas Cecil, A.M.I.Mech.E., 12, Salisbury street, Warrington.

Macdonald, James, Government Marine Surveyor's Office, G.P.O. building, Hong-Kong, China.

Makower, Ernest S., 8, Cambridge terrace, Regent's Park, N.W. 1.

Matthews, Dr. Joseph Merritt, 5, Berwyn street, East Orange, New Jersey, U.S.A.

Mawson, George Thomas, The Dunes, Marve, Salsette, Bombay, India.

Mews, Walter, Loxdale, Portslade, Sussex.

Molson, John Cavendish, M.D., L.R.C.P., F.C.S., The Gables, Hayward's Heath, Sussex.

Moore, William Withers, 32, Cleveland square, Hyde Park, W. 2.

Muto, Sanji, Kanegafuchi Spinning Company, Ltd., Hiogo, Japan.

Naidu, Mallem Chengalvarayulu, 1A, 36th street, Rangoon, Burma.

Nashipur, Maharaja of (Ranajit Sinha), Nashipur Rajbati, Nashipur, District Murshidabad, Bengal, India.

Nicholson, Harry, B.Sc., 30, Emanuel avenue, Acton, W. 3.

O'Leary, Very Rev. Peter J., Summerhill College, Sligo, Ireland.

Poulsson, Ths. H., Bredgt 5, Stavanger, Norway.

Richardson, Robert Taylor, J.P., The Starlings, Barnard Castle, Co. Durham.

Rowell, Herbert, M.Inst.C.E., M.I.N.A., The Manor House, Jesmond, Newcastle-on-Tyne.

Ruthen, Charles Tamlin, L.R.I.B.A. M.S.A., Bank chambers, Heathfield street, Swansea; and 33, Furnival street, Holborn, E.C. 1, and H.M. Office of Works, Storey's gate, S.W. 1.

Santosh, Raja of (Manmatha Nath Ray Chowdhury), Santosh, Tangail, District Mymensingh, Bengal, India.

Scott, James Lang, Twynholm, Bramley, Surrey.

Shewan, Hon. Robert Gordon, Messrs. Shewan, Tomes & Co., Hong-Kong, China.

Sneath, William H., Electric Furnace Products Co., Sande, Ryfylke, Norway.

Solman, Harry, 13, Ironmonger lane, E.C. 2.

Starr, Louis, M.D., LL.D., 123, Pall Mall, S.W. 1.; and Philadelphia, U.S.A.

Tait, William Archer, D.Sc., M.Inst.C.E., 9, Victoria street, S.W. 1.

Tarlton, Edward Smedley, Kumardubi Engineering Works, Barakar P.O., India.

Tobutt, John James, 67, Holland road, Willesden, N.W. 10.

Waite, Captain C. S., C.I.E., care of Railway Board, Delhi, India.

Wee Guan Toh, Sandakan, British North Borneo.

White, James, Commission of Conservation, Ottawa, Canada.

Wilcock, Arthur, 25, Hanover house, Regent's Park, N.W. 8.

Wilson, Anthony, J.P., Middle Ruddings, Braithwaite, near Keswick, Cumberland.

Wilson, Leonard, 926, Pennsylvania avenue, N.W., Washington, D.C., U.S.A.

Wood, Sir Henry Trueman, M.A., 3, Prince Edward's Mansions, W. 2.

Wright, A. J., L.D.S., D.M.D., 76, William street, Perth, Western Australia.

The CHAIRMAN delivered the following

ADDRESS.

This is the opening Meeting of the 164th Annual Session of this Society, and at the outset I desire to express my appreciation of the honour that my colleagues on the Council have conferred upon me in electing me to this Chair. The position of Chairman of the Council of the Royal Society of Arts is one of great responsibility, and it is no light task to address a Society before whom even the redoubtable Dr. Johnson failed when he essayed to speak, his flowers of oratory forsaking him, as he himself expressed it. I fear, moreover, that I shall not find it easy to reach the high standard set me by my eminent predecessors; but, relying on your kind forbearance, I will endeavour to do my best.

It is with much regret that I have to draw attention to the great loss that the Society has sustained through the resignation of Sir Henry Trueman Wood of his office as Secretary, which office he has held for a period of no less than thirty-eight years. This period exceeds by as much as eight years the service of any one of the twelve gentlemen who have held that important position since the Society was founded in 1754. Indeed, for so long and so intimately has Sir Henry been associated with all its activities that for us moderns it seems almost impossible to think of the Society without him.

You will, however, I am sure, all be pleased to learn that, though Sir Henry Wood has retired from the Secretaryship, he has been nominated as a Fellow of the Society, and will, we hope, shortly rejoin the Council in a new capacity. Consequently we expect still to enjoy his kindly presence at our meetings, and to have the great advantage of his ripe experience in our deliberations.

I have also great pleasure in being able to announce that in commemoration of Sir Henry Wood's long, arduous, and faithful service to the Society, it has been decided to found a Sir Henry Trueman Wood Lecture, to be given annually in this room by some eminent person, and that the inaugural lecture of this series will be given on December 5th by my distinguished predecessor in the Chair, Sir Dugald Clerk. I am sure that you will all agree that no one better could be found to give the first of these lectures, and I am sure also that you will not wish to let this, our first opportunity, pass without congratulating Sir Dugald himself on the honour which has recently been bestowed upon him by the King for his services to the nation.

Finally, before entering upon the subject-proper of my address, I desire to bring to your notice that we have appointed as our new Secretary, Mr. G. K. Menzies, who is responsible for having prepared the excellent programme for the new session that has been circulated amongst you. Mr. Menzies will undoubtedly have a difficult task in succeeding so experienced and so universally revered a predecessor as Sir Henry Wood, but he has had the advantage of serving under Sir Henry as Assistant Secretary for the past nine years, and has therefore a unique knowledge of what is wanted in a position which has been held by a number of very zealous officials, and for which, as you will perhaps remember, no less a personage than Oliver Goldsmith was once an unsuccessful candidate.

SCIENCE AND ITS FUNCTIONS.

In considering what subject I should choose for my address on this occasion I have been mindful of the objects of the Society which, as you know, exists for the encouragement of Arts, Manufactures, and Commerce.

In this connection the word "Arts" must not, of course, be restricted to its æsthetic sense, but should be interpreted in its widest possible meaning, so as to include the mechanical, industrial, and useful arts generally, and all those varied descriptions of activity that are the business of the artificer of every trade and of every denomination. Now, as I propose to show you, what is at the base of all the arts, as also of all manufactures, and as commerce consists of dealings in these manufactures, at the base of all commerce as well, is "Science." Without

science neither arts, manufactures, nor commerce could ever have existed at all, and without science none of these, as existing, could make any progress. It is, therefore, I hope, not inappropriate if I address myself this afternoon to some discussion of science and its functions. Now, what is science, and what are its functions? Huxley has defined "science" as "trained and organised common-sense." From an etymological point of view the word is synonymous with learning and knowledge, but in general usage a more restricted and definite meaning has been adopted, and in ordinary parlance by "science" we mean "natural science," or the systematised knowledge of natural phenomena and the relations that exist between them. Now, although this does not seem to be fully apprehended by the multitude, it is to science, understood in this sense, that is due the whole material progress of mankind from the earliest times. Primitive man may not himself have been conscious of the fact, but even in his earliest endeavours to meet the exigencies of his condition, it was science that he called to his aid. It was his faculty to observe natural phenomena and to adapt these phenomena to his needs, that first differentiated him from the beasts of the field.

From this faculty arose his use of weapons, fashioned by himself, for the chase and for defence against his enemies. Hence begot he the use of the sling and missile, and of the bow and arrow. Hence sprang his use of fire to cook his food, to light his way after dark, to bake and harden his bricks and tiles, his earthenware pots and utensils, to reduce his metals from the ore, and to fashion his bronze and his iron swords and spears. By what was, in fact, scientific observation he learnt to adapt the millstone to grind his corn, and the grindstone to sharpen his tools. Much systematised knowledge must have been acquired and put to use by primitive man, in the practice of prehistoric agriculture and in the production of instruments such as the spade, the hoe, the axe, the plough, and the reaping-hook, which he designed for tilling the ground and garnering the harvest. At some period the wheel must have been first applied to the primitive cart, and the canoe and coracle must have been fashioned for transit over rivers, and for navigation on lake and sea. Then there is the domestication of animals, their breeding, and the training of some of the species to carry burdens and to afford tractive and other assistance to their masters.

At an early age in these northern climates man must have discovered some method of tanning to preserve the skins in which he had perforce to clothe his body, while later he invented the weaving of rude cloth, sewing, and other similar devices. All this we learn from the remains left behind him by primitive man in the caves in which he lived and died, and in the sepulchres in which he was in the end laid to rest. And so man progressed in developing his powers and in applying to his requirements the things that he found around him, until he reached the comparatively high state of civilisation of which we learn from the Bible narrative and other ancient scripts, from the engraved stones of the Chaldeans, the moulded tiles with their cuneiform lettering of the Assyrians, from the Papyri and hieroglyphics of the Egyptians, and the great architectural remains of Babylon, Nineveh, Cnossus, and Egypt. In all of these we see the results of the observation of natural forces and phenomena, and their adaptation to human needs; in all of them we discern the first fruits of applied knowledge, in all of them we have illustrations of the functions of elementary science.

So far we have only discussed the considerations that moved early man to apply scientific methods to the improvement of his material condition, but at a very early date other things were also attracting his attention. The nature, phases, and movements of the sun and moon, and the other heavenly bodies, were objects for his notice and speculation, as also the structure, position, and relation to the rest of the universe of his own earth. These occupied his thoughts and excited his wonder, quite apart from utilitarian considerations, and were the beginnings of pure as distinct from applied science.

Since the earliest times, man, like his poor relation the monkey, has always been of a curious disposition, and has wanted to know the why and wherefore, as well as the mechanism of all the phenomena that he sees about him. No doubt much early science, especially in the fields of astronomy and alchemy, was practised as a cult, with a view to impressing and mystifying the common people, but at the back of it all there can be little question that the great force that impelled inquiry into nature, both in ancient times and in the modern world, was curiosity, which in itself is probably of all human emotions the one that has been most conducive both to intellectual and to material progress.

And now, with the appearance in history

of that wonderful people the Greeks, we come for the first time in personal contact with the scientific thoughts and the scientific theories of individual philosophers. Prior to that period there must have been scientific thinkers, but we have no distinct record of what were their scientific ideas. All that remains are portions of some of their material constructions, and some accounts of others that time and decay have destroyed. Thales of Miletus, one of the seven wise men of the Grecian golden age, though he lived some 600 years before our era, is no mere name. He was the founder of the physical school of Greek philosophy, who first began to consider the nature of things, and was the first to observe electrical action. To Democritus, a Greek of the fourth century B.C., we owe the earliest ideas about matter; while to Hippocrates, another early Greek, are due the beginnings of medicine and biology. To him is ascribed the immortal and pregnant phrase that while "Life is short, Art is long, Opportunity fleeting, Experiment uncertain, Judgment difficult"—an aphorism in which is summed up for all time the difficulties with which the scientific investigator has to contend. And so we pass on to that most famous of classical philosophers, Aristotle, whose writings have done more than that of any other man to influence the progress of science, and whose authority was so great that it bound the scientific world in iron fetters for centuries. In the great library and museum which was founded in the third century B.C., by Ptolemy at Alexandria, then the intellectual and commercial capital of the Grecian world, we find the apotheosis of Greek scientific activity. Here were preserved all the scientific writings and records that a world-wide search had enabled the founder to collect. Here were taught the philosophy of Aristotle and the geometry of Euclid. Here Claudius Ptolemy experimented in optics, and wrote his great work on the construction of the heavens. Here Eratosthenes measured the earth. Here Ctesibius invented the fire-engine, and Hero the first steam-engine, which it is interesting to note was a simple form of steam turbine. Here worked Archimedes, the most famous mathematician and physicist of the ancient world, who laid the foundation of hydrostatics, elucidated the theory of the lever, and invented the burning-glass and the screw-pump which still bears his name. As a man of science the world produced no equal to him for nearly two thousand years. But the days of the great library were numbered, and within those marble halls the drip of the water clocks of Apollonius were counting drop by drop, and second by second, the approach of the catastrophe. During the siege of Alexandria by Julius Cæsar, the library and all its contents were burnt—a fitting funeral pyre to the glory that was Greece.

The Romans made no contributions to pure science at all to be compared with those of the Greeks. They were a practical rather than a speculative people, and were great builders, engineers, and road-makers. Size, solidity, and quantity rather than novelty were the outstanding features of their scientific work. They were not like the Greeks, ever seeking after some new thing.

When Rome fell into decay, and the gloom of the dark ages settled down upon Europe, there was for a time an almost complete halt in the progress of science. True, some vestige of learning still struggled to maintain itself in what was left of the Alexandrian library, but this was finally extinguished by the latter's second destruction by order of the Arabian Khalif, Omar. After this, it is somewhat surprising that the next revival in scientific investigation took place amongst the Arabians themselves, now become a highly cultured people. To this revival we owe the invention of algebra, the beginning of systematic chemistry, and much new work in astronomy, medicine, mechanics, and metallurgy. One of the most famous of the Arabian experimental philosophers was Alhazan, who lived shortly before the Norman Conquest of England.

Of all scientific inventions perhaps the one, and a very simple one, too, that has most influenced the history of the world is that of printing. When all literature had to be laboriously copied by hand, it is obvious that books must have been scarce and expensive, and could not be widely circulated. Printing changed all that, and rendered for ever impossible the recurrence of such a disaster to civilisation as the burning of the Alexandrian Library, where, owing to there being no duplicates, much of the world's knowledge was totally lost. Printing has, no doubt, recorded much more trash than wisdom, but it is difficult to appreciate what the world would be like to-day without our libraries, our books, and our newspapers. Life would certainly be very different from what it is. More important than that, however, is the enormous impetus that printing gave and still gives to the diffusion of knowledge, and the effect of this on scientific and industrial progress. When, there-

fore, there began in Europe that great revival of learning known as the Renaissance, it was the printing press that became its principal coadjutor, and caused things to move at a rate much faster and on a scale much larger than ever before. It was with fundamental concepts that the new learning had first of all to contend, particularly with the geocentric theory of the universe, which gave to the earth and to human affairs quite an undue importance, and also with the authority of Aristotle which had become an article of faith and defied all new ideas. Both of these lost causes were defended with the full force of the Roman Church, with a consequent loss of prestige to the latter, which had not a little to do with the success of the Reformation. Polemical questions such as these, however, have but slight connection with the objects of our Society, so it is unnecessary to dwell upon them here. By the end of the sixteenth century experimental science, as opposed to the barren speculations of the school men, was again being practised in Europe with noteworthy results, while, a little later, Francis Bacon published his famous "Novum Organon," and thus became the apostle of the revival of this experimental method of attacking scientific problems. On this method, which had been practically abandoned for some hundreds of years, all modern science is based, and as soon as its practice recommenced results of the highest importance began rapidly to accumulate. How a dread of the tentacles of "authority" still lingered in scientific circles is, however, to be seen in the fact that when the Royal Society was founded in 1663, the Fellows took for their motto the words, "Nullius in Verba," an excerpt from a line in Horace which reads, "Not pledged to swear by the words of any master." To-day it is difficult to realise what a hold authority had come to have on even scientific ideas, and how even as late as the seventeenth century, antiquated and frequently unsound scientific principles, as enunciated in the writings of Aristotle, were still regarded as something that had to be faced when dealing with new problems.

And now we have arrived at a period when there commenced those organised efforts in scientific investigation, and those widespread and continuous endeavours to apply the results thus obtained to practical ends, that have produced during the last two centuries such marked effects on civilisation. We have now, in fact, a better opportunity than ever before of seeing what are the functions of science.

To arrive at some measure of the vast changes that have been brought about, let us consider how matters stood one hundred and fifty years ago, say in 1754, the year in which our Society of Arts was founded. At that date the steam-engine had not yet assumed a practical form, and apart from some small use of water and wind power, when mechanical work had to be done this was accomplished by the aid of the muscular effort of men and animals. The question of power supply was, in fact, in the same condition that had existed for thousands of years, and, in consequence, the employment of machinery of all descriptions that required power to drive it was extremely limited. Nor as regards travel for persons, or transit for goods, were things very different. The steamship was unthought of, and ocean journeying was no faster, and but little more certain, than in the days of Columbus. Railways in the modern sense were non-existent, and even the coaching era had scarcely begun. Travelling of all sorts was no more rapid or more convenient than in the days of the Romans. Indeed, emperors such as Hadrian and Severus, who visited this country in late classical times, probably made the journey to and from Rome quite as expeditiously, and very likely even much more comfortably, than did any traveller of the eighteenth century. Furthermore, at the time of which I speak, the communication of intelligence was limited to the speed at which postmen could travel, for, of course, there were no electric telegraphs, such as have shortened the time of communication with the ends of the earth to a few seconds, and have reduced even ambassadors to the status of clerks at the hourly beck and call of the Home Government. In the eighteenth century, moreover, illuminating gas and electric light had still to be invented, public lighting was practically non-existent, and even in London, and other large cities, linkmen with torches were required to light the passenger to his home after dark. If printing was in use it was slow and expensive, without any of the modern mechanical, photographic, and other adjuncts that have rendered possible our numerous newspapers and the other derivatives of the press. Nor were there any proper systems either for water-supply or for the disposal of sewage. Disease, born of filth and neglect, stalked through the land practically unchecked. Medicine was still almost entirely empiric. Little or nothing was known of the causes and nature of illness, of infection by bacilli, or of treatment by inoculation. Anæsthetics had not yet been applied,

and the marvels of modern surgery were undreamt of. It would be easy to multiply instances, but in the aggregate it is not inaccurate to state that at the time this Society was founded the general mode of life had not much improved on what obtained in civilised Europe in the days of the Antonines, while, in some respects, it fell much short of this.

To-day we live altogether in a different world, in an age of travel accelerated by steam, petrol and electricity; of railways on the level, overhead and in tubes; of trams and motor omnibuses, of bicycles and motor-cars; of steel ships and steel bridges; of mills and factories, with their products of every possible description; of telegraphs by wire and wireless; of telephones; hourly newspaper editions and tape machines; of electric light indoors and outside; electric power for every purpose, from carrying us upstairs to brushing our hair and our boots; of gas fires and gas cookers; of electric bells and electro plate; of automatic machines and thermos flasks; of pianos, pianolas, concertinas and gramophones; of kodaks, snapshots, and cinematographs; of fountain-pens, sewing-machines, typewriters, lawn-mowers, knife-grinders, vacuum cleaners, and barographs; of cigarettes and lucifer matches, which are much newer than many people think; of innumerable new and cheap textile fabrics, of plate glass, aluminium, indiarubber, celluloid, vulcanite, and all manner of new artificial materials; of laughing gas for having a tooth out, of chloroform and ether for more serious operations; of X-rays for inspecting our interiors; of dozens of new medicines for every ailment, and ailments with new names discovered every day; of balloons and aeroplanes, in which we may all soon be travelling; besides all the masses of diverse machinery used in manufacture, in agriculture, and in the arts. All these things, as well as many more, are younger than our Royal Society of Arts.

It has been the fashion to divide what we understand by science into two portions, pure science and applied science; but these are only halves of one great whole. Pure science, which is the domain of the research worker and the discoverer, supplies the data, physical, chemical, and mechanical, which it is the function of applied science to turn to account for practical utilitarian purposes. For this latter operation are required the services of the inventor and the engineer, and other experts of a similar character.

Even great scientific discoveries have in some cases been made by chance, but generally only by men of marked intuition and acutely developed powers of observation. More often they have been the result of prolonged thought, and laborious and patient investigation, with delicate experiments. Many have been the issue of elaborate mathematical reasoning. As subjects become more complex, complete knowledge of what has been done before in the same field is more and more necessary. One of the most fruitful sources of new discovery in all branches of science in modern times has been the greater attention paid to quantitative as against merely qualitative research, very accurate measurements of every kind being one of the special features of present-day research methods. A noteworthy point is that the results of research are cumulative, one discovery almost invariably leading to others in course of time.

One of the most exasperating questions that can be put to a scientific man who has just discovered some new thing, and at the same time a question that nearly always is put to him, is "What is the use of it?" Faraday's reply, when such an inquiry was made of him in regard to his discovery of electro-magnetic induction, is a good one. Like many a wise man before him, he replied to the question by asking another. This was: "What is the use of a baby?" As a matter of experience all discoveries in pure science, however recondite and however seemingly useless at the moment, find their practical application sooner or later. It may not be for years or even for centuries, but in its own time the application comes. Invention is a faculty of the imagination; the inventive temperament being akin to the artistic temperatment, and real inventors, like true artists, are born and not made. In order to be great, both must have creative powers in a high degree. Unless gifted at birth with the inventive afflatus, the ordinary man can no more by taking thought make himself an inventor than he can add a cubit to his stature. At the same time the inventor, to be fully successful, must be suitably educated. By study and the acquisition of knowledge he widens his scope, and can apply his gifts in fields of invention to which, without such knowledge, he could not hope to aspire. At the same time, it is a noticeable and curious fact that many great inventions have been made by men whose ordinary vocations were quite outside the particular field in which their inventions applied. This is no doubt a case of the fresh mind of the outsider looking at things from a new aspect.

whereas those who are daily working in any particular line are apt to get into a groove, and to be trammelled by usage and convention. Perseverance, and a capacity for continuity in keeping to one subject, are outstanding qualities to be observed in all successful inventors. Many with brilliant ideas fail for lack of these. As has been justly said, great discoveries are never, and great inventions very seldom, the work of a single individual. Both are usually the result of numerous separate contributions by different workers, who are often simultaneously in pursuit of the same object. With regard to inventions more especially, there are periods when certain definite advances are, so to speak, in the air. In such cases many persons are working at the same problem at the same time, and it is sometimes very much a question of luck who it is who first arrives at a successful solution. It is for this reason that patent cases in the Law Courts often turn upon what lawyers term "the state of the art" at the moment. Instances of concurrence of this nature are numerous, as when Morse, Wheatstone, and Cooke were all simultaneously engaged in rendering practicable the electric telegraph. Similarly, Graham Bell and Elisha Gray were almost neck and neck in the invention of the first practical telephone.

The fact is that, at certain periods, the general state of progress, both in pure and in applied science, renders particular inventions possible, with the result that a number of persons gifted with the necessary imagination almost simultaneously attack the problem. In such cases if one individual inventor had not succeeded, it is probable that another would have done so, though perhaps in some slightly different manner.

For these reasons in all these cases it is very difficult, if not impossible, justly to apportion the credit. The public and the press usually award it all to the individual who makes the first practical and commercial success, being entirely ignorant of all the previous stages that have led up to the final result, and oblivious of the fact that, without the vast amount of previous research by other workers, the final inventor would never have had the data wherewith to achieve what he did.

On the other hand, a contrary and equally mistaken view is not seldom taken by the workers in pure science, who, absorbed in the intricacies of their own achievements, are prone to underrate what the actual inventor accomplishes, usually by slow degrees, and with infinite pains and patience. They further do not understand what a long step there is between the mere idea and the worked-out invention, and how much labour, practical ingenuity, and perseverance, and also how much money an invention usually requires to make it successful, and to get it taken up industrially. Indeed, this last-mentioned commercial operation is frequently the most difficult of all to bring about, particularly as it is not common for inventors to be good men of business.

The history of particular inventions is frequently instructive, and a good instance is that of wireless telegraphy, which is comparatively recent, so that we know all about it, and can follow accurately each single step in its development.

It moreover shows how pure and applied science are indissolubly interwoven, and how the one is dependent upon the other.

According to modern views, enunciated in the first instance about the year 1807 by Thomas Young, light consists of undulations or wave motions in a hypothetical ultra-material substance, known as the ether, which is supposed to fill all space, permeating the solid earth, the planets, the stars, and all material objects, and reaching to the utmost limits of the universe. Just as sound is known to be a wave motion in the air, so light is believed to be a wave motion in this hypothetical ether. About the year 1870 James Clerk Maxwell, Professor of Physics at the Cavendish Laboratory at Cambridge, chiefly by mathematical reasoning, showed the close connection between electricity, magnetism, and light, by demonstrating that all three could be explained on the basis of motions and stresses in the ether. Thus, according to Maxwell, light was an electro-magnetic phenomenon, and consisted of disturbances in the ether of exceedingly short wave length, whereas longer waves and stresses in the same medium explained the phenomena of electricity and magnetism.

As mentioned, Clerk Maxwell's discovery lay purely in the land of theory, discovered mathematically, and he attempted no experimental proof. Some twenty years later Heinrich Hertz, by a series of most beautiful experiments, proved the truth of Maxwell's theory. By means of suitable apparatus he first of all created electro-magnetic waves, and then with other apparatus he detected them, showing that they could be reflected and refracted, and, in fact, obeyed all the laws with which light is known to comply. Indeed, so completely was this accomplished, that, on hearing of it, Lord Kelvin exclaimed

that Hertz had annexed the whole science of optics to the domain of electricity.

Up to this stage nothing in these investigations had hinted even in the slightest degree at any useful application. Neither Young, nor Maxwell, nor Hertz, was moved by any other ambition than a curiosity to explore the nature of things. On the other hand, had it not been for their labours, what was to follow could not possibly have occurred.

Hertz died young, almost immediately after making the experiments to which allusion has been made, but his work was taken up and largely extended in this country by Sir Oliver Lodge. Hertz's experiments had been on an exceedingly small scale, while Lodge employed, for creating his waves, methods which gave a much greater power; moreover, as a detector of these waves, Lodge used an exceedingly delicate instrument, which he christened the coherer. This was due to a discovery by Branley, of Paris, who also was investigating nature without any ulterior utilitarian aims.

Lodge, no doubt, was impelled by similar motives, but having a practical mind he threw out the suggestion that the Hertzian waves might possibly be employed for signalling. Indeed, he went so far, at a lecture which he gave at the Royal Institution in 1894, as actually to ring a bell by this means from one end of the building to the other, through the thickness of several partition walls. In the same year, at the British Association meeting at Oxford, he transmitted similar signals over yet greater distances.

These experiments of Lodge led several persons to consider whether the method was not applicable to telegraphy, but nothing practical was done until Mr. Marconi, who was acquainted with the work of both Hertz and of Lodge, and was impressed with the possible commercial value of the idea, came upon the scene, and with great skill very soon showed that it was feasible by Hertzian waves to telegraph across the Channel, and even over much longer distances.

The rest of the history of wireless telegraphy, very interesting though it is, does not concern us here, for what I wish to impress upon you is how, in this instance, as in many others, researches and experiments in pure science, which, so far as their authors could see, showed not the faintest sign of any practical application, led in time to inventions of the greatest possible public utility. Many years elapsed between the researches and theories of Young and Maxwell, the experiments of Hertz, and the advent of practical wireless, and, when it came, all the three original investigators were dead; yet, unless these three great men had evolved their brilliant ideas and worked them out as they did, wireless telegraphy had never been. How difficult it is for the unitiated to realise the importance and the practical potentialities of some discoveries in physics at the moment of their birth, may be made plain by a few words about the remarkable developments that have taken place during the past few years in that department of science known as molecular physics. Up to comparatively recently the theory of the atomic structure of matter, and the idea of the indestructibility of the atom, that smallest material particle that was thought possible to exist, still held its own. First enunciated more than two thousand years ago by the Greek Democritus, developed later by another Greek philosopher, Epicurus, and popularised by the Roman poet Lucretius in his celebrated poem, "De Natura Rerum"—concerning the nature of things—this theory of matter was put on a proper scientific basis by the English chemist, Dalton, rather more than one hundred years ago. Quickly following the discovery of the X-rays by Professor Röntgen in 1895, and of radioactivity by Professor Becquerel a few months later, came a most surprising development, indeed one of the most remarkable in the whole history of science. Mainly owing to the labours of Sir Joseph Thomson and his Cambridge school of experimenters, starting from the previous researches of Sir William Crookes, we now know that the atoms, once called the ultimate atoms, so far from being the indivisible entities as was once thought, are, each individual one of them, something very like a complete solar system, comprising a positively electrified sun or nucleus and a number of negatively electrified electrons or planets. More than this, though the whole atom is so small that it is quite invisible to the most powerful microscope, and that it would take at least three million atoms, perhaps ten or twenty times as many, set close together in a straight line, to cover a single inch, the constituent electrons are so much smaller that, though contained within the compass of the atom, they are as distant from one another, relatively to their size, certainly as are the earth and the moon, and possibly as the sun and the planets. The imagination reels at such an illustration of the microcosm of the infinitely small, just as it reels at the macrocosm of infinitely large astronomical

space and its population of innumerable stars; but in nature, as has been truly said, the adjectives large and small have no meaning. In nature there is nothing absolutely great, and there is nothing absolutely little. Whether it be a matter of the dimensions of space or of the lapse of time, all is relative. To us humans, space is measured in terms relative to the dimensions of our bodies, time in periods relative to the duration of our lives. To us things appear large or small, periods long or short, but these are appearances only and have no absolute reality.

Now to those who have not studied the question all this must seem very remote from the practical politics of applied science, such as we make use of in our daily life. But it is not so, for it is to these almost infinitely small negative electrons that we owe the Röntgen rays. When propelled at the incredible velocity of something about fifty thousand miles per second, which they attain under electrical stimulation inside a Crookes vacuum tube, and caused to bombard a piece of metal, they create these rays in much the same way that the bullets from a machine-gun may rattle on a target and thus create sound. The Röntgen rays themselves are a description of light, which, until artificially produced by man in the manner described, had never been observed in nature, and, indeed, had perhaps never previously existed in the whole history of the universe. Their practical utility is, however, now universally realised, and in surgery and medicine they are in everyday demand.

Now, not only have these abstruse and seemingly quite academic discoveries about the electrical structure of the atom, and the properties of its constituent parts, brought about great improvements during the last few years in the design and use of Röntgen-ray tubes, but they have also borne practical fruit in other directions, as, for instance, in what is to-day much the most sensitive and reliable apparatus for receiving wireless telegraph signals. Their further utility, moreover, is just now beginning to make itself apparent, and quite recently they have been applied by Sir Joseph Thomson to an entirely novel form of chemical analysis, the possibilities of which it is as yet too early to estimate. Anyway, we see how in a space of only about twenty years, discoveries of apparently purely academic interest, in perhaps the most abstruse of all lines of scientific investigation, are already beginning to be usefully applied. We see how the function of science to be utilitarian obtains just as much in the case of highly recondite investigations, as in those that are more simple and in which the practical applications are more obvious.

An interesting question is what manner of men they were who made our great scientific discoveries, and what were their vocations or professions in ordinary life. To go into this fully is beyond the time at my disposal, but the following information with regard to the authors of a few of our most famous discoveries is instructive, especially in view of present-day educational controversies. An outstanding feature is that many of them had no professional connection with science at all, but were amateurs pure and simple. Among these may be mentioned Robert Boyle, the famous discoverer of the law of the expansion of gases, who was a landed proprietor educated at Eton, and has been described as "the father of chemistry and brother of the Earl of Cork." Henry Cavendish also, who discovered hydrogen and the composition of water, and did much original work in electricity, besides devising the celebrated Cavendish experiment for ascertaining the weight of the earth, was a pure amateur, being the grandson of the second Duke of Devonshire. He was very eccentric and very rich. Sir William Herschell, the famous astronomer, was by profession an organist and a teacher of music. Priestly, who discovered oxygen, was a Presbyterian minister. Dalton, the distinguished chemist who elaborated the atomic theory, was an assistant schoolmaster. Benjamin Franklin, who with a kite drew electricity from the clouds and thus established the identity between electricity and lightning, was a self-educated printer. Benjamin Thomson, afterwards Count Rumford, who contributed considerably to the theory of heat, began life as an assistant in a store. Franklin became United States Ambassador to England, while Rumford reorganised the Kingdom of Bavaria, and the pair are, perhaps, the only politicians—or, perhaps in their case, one ought rather to say statesmen—who ever contributed anything of value to science. James Prescott Joule, who was the experimental founder of the great theory of the conservation of energy, and who first determined the mechanical equivalent of heat, was likewise an amateur, being by profession a brewer.

Others were of the medical profession, as the famous Dr. Gilbert, of Colchester, physician to Queen Elizabeth, whose works on electricity and whose book, "De Magnete," are a monument to his industry and discernment. Thomas Young, the great protagonist of the luminiferous

ether and of the undulatory theory of light, also was a doctor. Sir Isaac Newton, on the other hand, was a student, and afterwards a professor, of Cambridge University, and finally Master of the Mint. Sir Humphry Davy and Faraday both made their great names at the Royal Institution, where they enjoyed facilities for experiment, which one would like to see greatly multiplied elsewhere. Both were of humble origin, Davy being the son of a wood-carver, who became assistant to a surgeon; and Faraday the son of a blacksmith, and a bookbinder's apprentice, who had the good fortune to attract Davy's attention and to become his assistant, and afterwards his successor. It is noteworthy that but few of these great men had the advantage of early scientific training.

The case of some of the world's greatest inventors is also interesting. James Watt began life as a mathematical instrument maker. George Stephenson was a colliery fireman who only learnt reading, writing, and arithmetic after he was grown up. Arkwright, the great inventor of cotton-spinning machinery, was a barber. Daguerre, one of the principal inventors of photography, a scene painter. Sturgeon, the inventor of the electro-magnet, was a private soldier, and carried out his earlier experiments within barrack walls. Morse, of telegraphic instrument and code fame, was a painter and sculptor. Alexander Graham Bell, the inventor of the telephone, a teacher of the deaf and dumb. David Hughes, the inventor of the type-printing telegraph and of the microphone, a professor of music. Edison, a railway newsboy, practically self-taught. William, afterwards Lord, Armstrong, the inventor of hydraulic power distribution, and celebrated for his gun, a practising solicitor till he was thirty-five years of age.

All this goes to show that, as already stated, inventors are born and not made; and that, at any rate in numerous cases, genius can dispense with teaching from outside. In fact it is not for men such as these that more education in science is to-day wanted, but rather for our masters, the politicians, the directors of public affairs, and the Government officials.

It is impossible to study the history of civilisation without recognising that scientific research and invention, with their innumerable and incalculable actions and reactions, constitute the soul of industrial progress. Consequently, if this progress is to be maintained, every inducement must be provided to encourage those who are capable of carrying on the work. Since the commencement of the world it is not to the masses but to the few exceptional individuals that all great advances have been due, and it is greatly to be deprecated that politicians who must, or, at any rate, should, know better, continue to flatter the so-called working-man by telling him that he alone is the creator of wealth. To those who know the facts such a suggestion is, of course, absurd. Still, it is highly necessary that the masses should be educated to learn that unless those who have the requisite capacity are afforded the necessary leisure and facilities to work at research and invention, industries can neither be developed nor even maintained in the face of the world's competition, and that the working-man himself will be the principal sufferer from the resulting stagnation and decay.

We hear at present a great deal about the avarice of capital and the extortionate profits of monopolists and patentees, and still more about the due reward of labour. At the same time but little is said as to the encouragement of ability, though the latter is really of paramount importance to the nation. For, whatever may be the case with capital, ability, if not encouraged at home, can easily take wings and fly to other lands, where it is better appreciated. Then home industries will languish, employment diminish, and where will labour be?

It is unfortunate that in this country of late years it has become a fashion to consider the making of large profits as almost a crime, for the working out of many industrial scientific processes and inventions can only be accomplished by great and prolonged expenditures, and the risking of vast sums of money, such as only very rich persons or companies can afford. The history of the fine chemical trade in Germany for some years before the war is a good case in point. Here very large sums were in some instances spent on the development of special processes. In many cases the money was lost, but the few speculations of this nature that succeeded recouped all that had been spent on the others, a single product in some instances bringing in an enormous net annual profit. This, again, enabled other similar problems to be attacked. With our system of taxation—income tax and super tax, and now excess profits tax in addition, and the jealousy and outcry that the making of large profits engenders—it is very difficult to arrive at such results in this country, and this undoubtedly is one of the main reasons for our backwardness in diverse directions. A remedy should be found in exempting from taxation all money spent in new scientific

developments. Otherwise, with stinted resources, we cannot expect to maintain our position.

There are two methods by which people acquire wealth. In one case they transfer other people's wealth out of these people's pockets into their own; in the other case they actually create wealth that did not previously exist. Though the first method may often be quite legitimate and even beneficial, it cannot, of course, be compared in importance with the second, for whosoever really creates wealth, not only enriches himself, but adds to the resources both of his own country and to those of mankind. Now one of the functions of science is to create that best of all descriptions of wealth, increased productivity, which it does through discovery and invention, and the enhanced command that man thereby obtains over nature. Thus the invention of the steam-engine by James Watt, and the three or four other men who were associated with him in that vast development, must have increased the wealth of Great Britain and of the world by many hundreds, if not thousands, of millions sterling. The Stephensons and their associates in the invention of the locomotive and its application to railways also cannot fall very far behind in this respect, while other inventions great and small all operate in a similar manner. Both those who make discoveries and those who make inventions are therefore in general well worthy of their hire, and in both categories it is seldom that they receive as remuneration for their work more than the merest modicum of the wealth that they create. This is a point that should not be forgotten, especially in these socialistic times, when much of the popular political teaching tends to uphold an opposite view.

This brings me to another point in connection with invention, and that is the injustice and the inexpediency, from a public point of view, of the present system whereby the Patent Office makes a large annual profit out of the fees paid by inventors. There might possibly be some justification for this were the money thus obtained spent on scientific education, on scientific libraries, or on some other object that would further invention and discovery. The money is, however, merged in the ordinary revenues of the country, and thus becomes a veritable tax on brains. It is, moreover, a tax on the cerebral activity of a class of men who are usually by no means overburdened with wealth. Though all inventors are fortunately not driven by poverty to such expedients as Palliser the potter, who actually had to burn his household furniture in order to provide heat for his furnace, still the majority of inventors are undoubtedly poor, and find the cost of protecting their inventions by patent, and still more of maintaining these patents when granted, a considerable strain upon their finances. The truth of this may be seen by the frequency with which patents are dropped merely in order to save the renewal fees, and the patentee in some cases deprived of profits to which he is justly entitled. Herein lies a possible and very desirable reform which this Society might perhaps do something to bring about.

We shall, however, never get justice done to science by the Government and its departments until some knowledge of science is made a compulsory part of the curriculum for the training of the Civil Service, and an important item in the entrance examinations. Only in this way shall we get the departments filled by men who realise what science means, and how it lies at the root of all material progress. There is an idea afloat in the political world, as also in the bureaucratic mind, that no man can at the same time be a master of science and a good administrator or organiser, either in public or commercial affairs. This idea probably originated from observation of scientific men of the scholastic and professorial types, whose training has been mainly directed to the art of teaching, and who have never had much opportunity of developing their faculties in the administrative sphere. To show, however, how false is the assumption, it is only necessary to mention two such names as those of Benjamin Franklin and Count Rumford, both of whom were consummate men of science and did very valuable original scientific work, but were also both prominent men of business and managed great political undertakings with remarkable success. Or, if we come to more modern times and turn to captains of industry, there are, without going out of this country, and only to mention one or two, such men as Joseph Whitworth, Henry Bessemer, William Armstrong, and Andrew Noble, all of whom had high scientific gifts and knowledge, and also were very successful in the organisation and administration of large industrial enterprises. Indeed, for any business employing technical methods, the ideal chief must necessarily be a man of scientific attainments, as it is only such a one who can properly weigh the pros and cons of the propositions put

before him by his technical staff, while what is even more important, it is only such a chief that can command the real respect of his employees, who will never have complete confidence in, or a proper veneration for, a leader whose scientific and technical knowledge and experience is in the aggregate less than their own. These considerations, of course, apply equally to Government departments which deal with scientific questions as to industrial undertakings carrying on technical processes or manufacture.

In obtaining Government support for the promotion of applied science, it is most necessary to beware of political interference.

The dangers that arise from this may be seen from the history of one or two typical industrial applications of science during the last century. Take, for instance, the application of mechanical power to road locomotion. In the period covered by the years 1820 to 1836 this made rapid strides, and towards the close of the period many steam-coaches were maintaining regular services between various centres in different parts of the country. In this, England was many years ahead of the rest of the world and a new, and what promised to be a very profitable industry was being developed. Parliament, however, at the instance of rival interests, passed hostile legislation which absolutely shut the whole movement down, and automobilism in this country was completely crushed, not to be heard of again for more than fifty years. When, moreover, a new beginning was made, the fresh start did not take place in England, its original home, where it was prohibited by law, but in France where legislation was more enlightened. In this way, owing entirely to the politicians, we lost an opportunity of becoming pioneers throughout the world of a completely new and what proved to be a gigantic industry, which might have brought to our manufacturers much wealth and to the working-classes much lucrative employment.

Or, to turn to another case, take the history of electric lighting and of the supply of electric power. Here again the development of a new scientific industry was greatly impeded by Parliamentary action. In 1882 this country was as far advanced in everything pertaining to the application of electricity as any other country on the globe. Indeed, many of the developments in this branch of science were peculiarly British, having originated in this country. Again, Parliament intervened, and with a mistaken idea of protecting the consumer from the dangers of monopoly, so effectually strangled the whole movement that for six years there were practically no consumers at all, as the conditions imposed on undertakers were so onerous that no one would risk the money required to institute a supply. In 1888 the political powers that were, realising their mistake, made some legislative amendments that enabled a start to be made; but it was then too late, for other countries had got ahead, and even then the electrical industry was still hampered by artificial conditions, some of which endure to the present day, with results that have been very inimical to proper development. There are other similar instances, such as the telephone, in regard to which the politicians have interfered to the detriment of progress.

To a Society such as this, whose object is the encouragement of the arts, science is mainly interesting from its pre-eminent value for purely materialistic ends, and it is therefore from this point of view that I have endeavoured to give some account of its functions. It must not, however, be supposed that science has not also a very high value, from an ethical standpoint. As Adam Smith wrote in his "Wealth of Nations" a century and a half ago, "Science is the great antidote to the poison of superstition"; moreover, science is, so far as the limitations of the human intellect will permit, a search for absolute truth. Accuracy is its foundation stone, acute observation and strict logic its most powerful agents. These have all an educational value of the highest importance. The study of nature and the pursuit of knowledge have, in addition, an elevating influence, and produce a breadth and a strength of mind that rise superior to material environment. This is well seen in the blameless lives of the great masters of science, and in the way that many of them sacrificed everything to their work. Some encountered persecution and even martyrdom for their ideas, and met their misfortunes with a fortitude quite equal to that shown by other men for their faith. Among the functions of science we must not therefore forget its moral power.

After delivering the address, the Chairman presented the Society's medals which were awarded for papers read during last Session.

At the Ordinary Meetings:—

Francis A. Hocking, B.Sc., Pharmaceutist to the London Hospital, "The War and Our Supply of Drugs."

SIR C. ARTHUR PEARSON, Bt., Chairman, Blinded Soldiers and Sailors Care Committee, "The Blind Sufferers from the War and their Future Employment."

LESLIE URQUHART, "The Economic Development of Russia and Britain's Interest therein."

In the Indian Section :—

JOHN AITON TODD, D.L., Professor of Economics, University College, Nottingham, "The World's Cotton Supply and India's Share in it."

In the Colonial Section :—

CAPTAIN PHILIPPE MILLET, Colonial Editor of *Le Temps*, "The Problems of French North Africa."

SIR HENRY TRUEMAN WOOD said the pleasant duty had fallen upon him of proposing a vote of thanks to the Chairman. He accepted that duty, and felt it a very great compliment to have been asked to undertake it, but he did so with a little regret, because Sir Dugald Clerk, the immediate predecessor of Mr. Campbell Swinton, was to have proposed the vote of thanks, but he had unfortunately been called away. The Chairman of the Council had, under the Society's rules, to address the Society at the opening meeting, originally mainly with the idea that he should indicate to the members the programme of the Society for the session and the course of its work during the year. For a good many years the Chairman of the Council had gone beyond that limited scope, and, instead of merely saying what the Society was going to do during the next six months, he had preferred to deal either with some special detail of the Society's work or with the general progress of the Society, taking its work as a whole and its future as a whole. The result had been that the Society had had a long series of most valuable and instructive addresses from its past Chairmen, some of the most distinguished men of their time. Amongst those addresses certainly that of the late Chairman of the Council, Sir Dugald Clerk, took a very high place, and the present Chairman therefore had to compete with work of a very high standard. He was sure, however, all the Fellows would agree that the brilliant survey of human progress with which Mr. Campbell Swinton had delighted them that afternoon was as worthy to take its place in the records of the Society as the addresses of any of Mr. Swinton's predecessors. Sometimes lately he had been inclined to think that a malignant influence was diverting scientific progress from its proper course, and causing it to devote itself to appliances and instruments for causing the greatest amount of misery to mankind, and the greatest anguish to individual men, instead of confining itself to its proper function of increasing human welfare and human happiness. There was every reason to believe, however, that science would soon get back to her proper duties, and he thought the news which had just been published of the great success that had attended the British Armies in France brought that happy period definitely nearer. To-day one might look forward to an earlier conclusion of the war than could have been hoped for yesterday, and he regarded it as a happy inauguration of the Society's session that that good news should come when the Society was actually beginning its work for the current session. The Chairman had given the members an example of his intellectual capacity, but beyond that he was, as many of those present knew and all his friends realised, a most admirable man of business; and he felt a little pride in the fact that the last service he rendered to the Society as Secretary was to convince Mr. Campbell Swinton that it was his duty to undertake the Chairmanship. He was very glad to say that Mr. Campbell Swinton's objections were overruled, with the result that the Society had a most excellent working head for the coming year. It was possible that his resignation from the Secretaryship would throw a little more work upon the Chairman, and partly for that reason it was essential that the Society should have a good man of business at its head, the Chairman of the Council being of course the practical head of the Society during his term of office. Such a man the Society had obtained, and he congratulated it on that fact. He also assured the Fellows that they might be perfectly well satisfied with the head of their executive staff. He had watched Mr. Menzies very carefully for the past nine years during which they had worked together, and he had tried to train him so that he might undertake the post of Secretary when he (Sir Henry Trueman Wood) had to resign. The Fellows might fully rely on Mr. Menzies' capacity and ability to carry on the work of the Society in the way in which it should be carried on. He begged leave to propose a very hearty vote of thanks to the Chairman, and asked those present to congratulate the Chairman, by their vote, upon the address he had just delivered, and to realise that they had the best man they could wish to have to carry on the very important work of the Society.

HIS GRACE THE ARCHBISHOP OF CANTERBURY, in seconding the motion, said that when he entered the room, anxious to hear what was to be said by one whom he had known from his birth, he little thought he would be called upon to do what was a most unwonted thing for him—to say a few words to scientific men upon a scientific paper. He was comforted, however, by the fact that the Chairman had reminded them that some of the best and most useful work that had been done in connection with science had been carried out by people who knew nothing about science; they were merely amateurs who had happened by accident to discover something of scientific importance. Therefore, those who had to confess themselves unscientific down to the soles of their boots were not to be

left without hope or without opportunity. Mr. Campbell Swinton's address had been extremely interesting to him, and he was sure must have been so to all those present that afternoon. He personally had known Mr. Campbell Swinton from the day of his birth till the present time, and had watched him adding laurel to laurel, and acquirement to service and service to acquirement, right through those years. The present address seemed to him a masterly piece of work, because it was one of the most difficult things in the world for a person who was conversant with a particular field of some great subject to traverse the whole subject in a large and general way without boring those who were not as expert as he was in its intricacies. No one could have found a single sentence in the address tedious or boring. On the contrary, Mr. Campbell Swinton had started two or three trains of thought which could be followed up, not in connection purely with the definitely scientific aspect which he gave them, but in a larger way. All that the Chairman had said about the contrast between the progress of science to-day and its progress at other periods, and the question whether or no our boasted progress had really got us as much further as we supposed in the pursuit of human knowledge and human attainment in the highest sense of usefulness, seemed to him particularly interesting at the present time. Those who had read the notable book published within the last few days, Lord Morley's "Reminiscences," would have noticed how he touched upon the very thoughts which Mr. Campbell Swinton had touched upon in his present address, as to whether or not we were now really in a better condition, in consequence of all our science and knowledge, than people were, say, in the days of the Antonines. Lord Morley treated the subject in a masterly way, and Mr. Campbell Swinton had given a striking illustration of the truth of the thoughts which Lord Morley threw out as a man of letters and a man of affairs. The other day he was asked whether he realised that when Julius Cæsar came to conquer Britain he walked here. There seemed no doubt that Julius Cæsar did not ride on a horse or come in a litter, and it puzzled people a little to think of the contrast now in the speed of travelling, and led them to wonder whether the world was better or worse for the expedition with which things could be carried out. That was a matter which offered a large field for thought. Mr. Campbell Swinton suggested another thought, which was one of great usefulness, by showing how mistaken it was to regard the acquisition of a certain piece of knowledge merely from its obvious utilitarian standpoint, and how the utility came in later—if the knowledge was there the time would come when it would take its place and find its use. Another thought was suggested in the address by the way in which Mr. Campbell Swinton dealt with the problem of the contemporary study of great questions, and contemporary—almost synchronous—invention by different men. It was not always that an exactly similar course of study was being pursued by those different men. Some instances given in the address, and certain others with which everyone was familiar, showed that men, following quite different routes, accidentally, it would seem, or by some extraordinary coincidence, arrived at the same practical conclusion at the same time, and the world was thus enriched by an invention which it was extremely difficult to allocate to a particular individual. He desired once again to express his appreciation of Mr. Campbell Swinton's address, and to rejoice in the thought that amateurs from outside might come in and touch on scientific matters without necessarily doing them harm, and sometimes even doing them good.

The resolution of thanks was put to the meeting by SIR HENRY TRUEMAN WOOD, and carried with acclamation.

THE CHAIRMAN thanked the mover and seconder of the resolution for their flattering remarks, and all those present for the appreciative way in which they had received the motion. He had just been thinking how sometimes circumstances altered cases. That afternoon he had very properly deplored the loss of literature that occurred owing to the burning of the great Library at Alexandria, but he could carry his mind back to a time when his sentiments were somewhat different. He could remember when it was part of his daily task to learn some Propositions of Euclid, and he remembered that at that period he did not deplore the loss of many of the books of Euclid—it was a matter of great satisfaction to him. That satisfaction was only tempered by a certain amount of fear that before his course of geometry had finished perhaps those other books might be found.

THE RESTORATION OF FORESTS DEVASTATED BY THE OPERATIONS OF WAR.

In an article on this subject in *La Nature*, M. A. Jolyet, Professor at the École Nationale des Eaux et Fôrets, says that the North-East of France is a well-wooded region, and it is natural that numerous forests should have suffered as a result of the operations of war. However, though the damage incurred may have been great, it does not follow that the forests must necessarily be destroyed.

A forest is not merely formed by the sum of the plants living therein, but also by the forest soil, or primitive soil modified by the existence of the forest, and by the sum of the plant and animal life there developed. The "état boisé" (wooded state) so produced represents a valuable capital, and it would be a serious mistake not to utilise it as soon as possible, for this state or condition, though surviving the destruction of the forest population, does not last for ever.

There are two methods of regenerating a forest in these conditions: one natural and the other artificial. The former is not profitable, being too long, whereas the interest of the owner lies in obtaining commercial timber from his forest as soon as possible.

The first point then to establish in restoring a forest damaged by war is whether the injured trees are definitely broken or merely bruised. In the first case they must be cut down level with the ground and, provided the species is a deciduous one and not too old, new shoots will then emerge from the stump. On the other hand, if the tree is a conifer, no shoots will be formed, but by cutting down the tree the danger of encouraging insect parasites will be avoided. In the second case also felling is almost always advisable, for a mutilated tree is not likely to produce healthy wood.

As a result of the felling, gaps of greater or less extent will occur. These it will be necessary to till up by means of appropriate species: (*a*) encouraging the natural reconstruction of the forest with wild species, or at any rate not impeding this by an excessive amount of cover—(*b*) capable of furnishing within a short period good marketable timber, the sale of which will enable the proprietor to put back the forest in its original state.

Next, the two following cases must be considered:—

(1) *Gaps of large extent.*—When the removal of damaged plants leaves a very big gap, it is advisable to plant, not merely a temporary, but also a robust species with light shade in order to allow the reconstitution of the original species (oak, hornbeam, maple, ash, fir, etc.). The majority of pines fulfil these requirements—the Austrian pine is particularly adapted to a thin chalk soil; in sandy soil, on the other hand, Scots pine does best. *Pinus Banksiana*, Lamb., in spite of the small value of its wood, is also recommended on account of its great hardiness, which favours a quick recovery. As these species all require light, the plantations must be fairly thin, the trees five to ten feet apart.

Clearings must then be made in succession, and in this way, while obtaining an easily marketable product, the forest will eventually be completely reconstructed and rendered capable of again yielding marketable timber in its turn.

(2) *Gaps of very small extent.*—When the gap left by the removal of the plants is not above twice the height of the surrounding trees in size, the use of pines, which require a particularly large clearing, is not possible. However, as the object is to plant trees capable of early utilisation, there are other species of conifers answering to this requirement, and among these the fir and spruce are preferable. Though they give a very thick shade, the pyramidal shape of their summits will give the minimum of inconvenience to the surrounding trees, especially to the deciduous species. The fir is most advisable from the cultural point of view and the spruce from the commercial standpoint. At the same time, this would be the best way to establish the fir in forests of deciduous trees, and could only add to the value of the forest as a whole.

The writer also recommends the white fir (*Abies concolor*, Lindl. and Gord.), characteristic for its hardiness and rapid growth. The wood, however, is mediocre, though perhaps not more so than that of the fir cultivated at a low altitude. The Douglas fir (*Pseudotsuga Douglasii*, Carr.) might also be recommended, as it furnishes a first-class wood and grows rapidly; but there are doubts as to its hardiness. In this connection the tested Colorado variety might be borne in mind, though it grows less rapidly.

If, finally, other deciduous species are preferred to the conifers mentioned above, one might use for the big clearings birch and false acacia instead of pines. On the other hand, in the case of the small gaps, beech, or better, ash, might be planted instead of firs, and especially sycamore, which can do with a fairly poor amount of light.

THE CORAL INDUSTRY OF JAPAN.

The coral industry of Japan has received a strong stimulus from the European war. Previously this country exported about half of its crude coral to Italy, where there was a steady demand for it on account of the practical exhaustion of the coral beds in the Mediterranean. Skilled Italian workmen carved the coral into the various forms demanded by the fashions and tastes of the Occident. As Italian-carved coral it was sold through Dutch distributors to the whole world.

Since the outbreak of the war, writes the United States Vice-Consul at Nagasaki, there has been a natural decrease in the demand for carved coral, but the chief difficulty encountered in supplying the market has been that of making direct shipments of crude coral from Japan to Italy. Usually it has been necessary to make one or two transhipments *en route*, with incidental expense and delays. This produced a decrease in the quantity exported to Italy. The resulting situation caused the Japanese to fall back on their own resources in undertaking to absorb the surplus of crude coral left in the home markets.

The Italian dominance in the coral industry has been due to priority in the field and to a knowledge of the styles of carving in demand among Occidental buyers. Japan has been handicapped, not by a lack of skill in carving (for it is in the domain of small carvings that Japan has been recognised as supreme), but by failure to have an up-to-date knowledge of Occidental fashions and tastes. It was only necessary to teach artisans already skilled in carving ivory and wood to work with a new medium. But the Japanese have not ventured to produce any manufactured coral except what was suited for sale in the home market. This has been practically limited to beads and netsuké (small buttons

used as ornaments on the strings of tobacco pouches). The beads are of all sizes and are sold in strings of three or four inches in length, as hair ornaments for women. Large single beads, from one-half to three-quarters of an inch in diameter, are used as the heads of large ornamental hairpins much in favour among Japanese women. In the manufacture of coral beads the Japanese are recognised as the equals, if not the superiors, of the Italian workmen.

A realisation of the opportunity created by the war for Japan to take the place of Italy in the production of carved coral has led the Japanese Government, through the marine experiment stations, to undertake the training of artisans in the carving of coral for sale in Europe and America. It is hoped by this measure to increase the value of coral exports from the £100,000 received each year for the crude coral exported, to £7,000,000 for exports consisting entirely of carved coral.

A special agent of the Imperial Fisheries Bureau is detailed to assist in the development of the industry in the Goto district of Nagasaki Prefecture, where new coral beds of exceptionally high productivity were recently discovered. He also has charge of the instruction of the apprentices, now about twenty in number, in the carving of coral. After the Goto district, the Provinces of Tosa, Satsuma, and Miyazaki follow in order of importance as centres of the coral industry.

The coral beds are worked by divers in the employ of a master diver, who receives the take as it comes in, grades it, and when a sufficient amount has been obtained, asks for bids on the lots of each grade. Representatives of the leading exporting and wholesale firms are always at hand during the season when the best coral is taken, to inspect the take and proffer bids. The total annual take is about 65,000 lb., valued at £140,000.

The colour of the coral has a great deal to do with the value placed upon it. The most expensive is "bokó," a pale quince colour. Single beads of this colour, suitable for manufacture into ornamental hairpins, bring from £2 to £10 each. The next colour in value is pink, followed by white, light red, and dark red.

OBITUARY.

Samuel Charles Phillips.—Mr. S. Charles Phillips, head of Messrs. S. C. Phillips, proprietors of the *Paper Maker* and other well-known trade publications, died, after a short illness, at his residence, Greenbank, Beaconsfield Villas, Brighton, on October 9th, in his fifty-fifth year. He was a recognised authority on the paper, board, and pulp industries, both at home and abroad, and he keenly interested himself in the search for, and utilisation of, new paper-making materials. He read three papers before the Society, namely: "The Use of Wood Pulp for Paper-making" (1905), "The Empire's Resources in Paper-making Materials" (1915), and "Paper Supplies as Affected by the War" (1916). He also took part in discussions at several other meetings of the Society. He was elected a Fellow of the Royal Society of Arts last year.

GENERAL NOTES.

Forest Products of Quebec.—The forests add over $15,000,000 every year to the production in the Province of Quebec. The forest reserves in this province, says the *Paper Maker*, total 107,997,513 acres. The pulp wood, lumber, shingles and laths make up the big annual production of the timber industries of this province. The pulp wood used in the province approximates a value of $4,000,000 per year. The woods used in the manufacture of pulp, to which this province adds a big annual contribution, are spruce, balsam, fir, hemlock, poplar, larch and jack pine. The pulp wood consumption in Quebec Province is the largest in Canada. The lumber production of Quebec exceeds usually a yearly value of $10,000,000. Quebec has one of the three biggest lumber, shingle and lath productions in Canada. The shingles produced in the province total an annual value of about $700,000. The lath output of Quebec exceeds a value of $225,000 annually. The total value of lumber, lath and shingles produced in the province in one year exceeds $15,000,000, a recent total being $15,758,529. About two-thirds of this total is in lumber and timber, the other third being in pulp wood, lath and shingles.

Scarcity of Coal in Havana.—According to the British Minister at Havana, a number of Cuban sugar mills are, owing to scarcity of coal, preparing to use oil fuel. Storage tanks have, in one or two instances, been purchased and installed, but things of the kind are naturally, at the moment, difficult to obtain. The cost of converting the furnaces is not serious. The railway companies are in a much worse plight through the shortage of solid fuel. The United Railways of Havana have 264 locomotives, and the cost of their conversion, estimated at 1,000 pesos for each locomotive, together with the cost of tanks and pipes, would absorb a considerable sum. There has been a good deal of prospecting for oil in the Province of Havana, and numerous claims have been registered, but so far only two wells have given actual results. The general impression seems to be, however, that the prospects are good. The output of the two wells at Bacuranco continues to increase.

LOCOMOTIVE DEVELOPMENT.—In his report for 1916, the General Manager of the South African Railways and Harbours makes the following comments upon locomotive development:—The further improvement of the locomotive boiler is a subject that has engaged the attention of mechanical engineers for some time. The superheater has added greatly to the steaming efficiency, and has neutralised the difficulties associated with the firing of large engines to maintain the pressure of steam necessary for the work required of a modern locomotive. But increased steam pressures are still desirable, and experiments are being conducted in different parts of the world with new boiler designs and other improvements calculated to develop the steaming efficiency and the steam pressure of the locomotive. That very high pressures can be raised and maintained by means of tube or pipe generators has already been established, but it has yet to be proved whether a generator of this type can be successfully adapted to locomotive practice. A generator on those lines has been designed by the Superintendent (Mechanical), Johannesburg, and inquiries are being made as to the practicability or otherwise of his proposals. The design involves a radical departure from present practice, and will require most careful investigation and consideration before further action is taken. In the experimental stage oil fuel may have to be used, but the object in view is to adapt the engine to burn coal dust, and that being so, the result of the advance that is being made in the United States with engines designed to use pulverised fuel is being watched with special interest, particularly in view of the fact that the use of such fuel eliminates fire hazard.

EXPORTS OF PRESERVED CODFISH FROM JAPAN.—H.M. Commercial Attaché at Yokohama writes that the Japanese Department of Agriculture and Commerce made efforts to develop the export trade in codfish from Japan prior to the war, and that during the last three years there has been a considerable increase in exports of this commodity to North and South America and the South Pacific Islands. Big fish are preferred for the export trade, and those caught off Horomushiro, Kurile Islands, are considered to be the best. Codfish are exported from Japan either salted, dried or tinned, the tinned variety being in greatest demand, followed by the salted. American salt is imported for preserving fish for export to America, as fish treated with Japanese salt do not satisfy the American taste.

RUSSIAN MERCANTILE MARINE.—The Canadian Trade Commissioner at Petrograd (Mr. C. F. Just) reports that with the elimination of German shipping interests as intermediaries in the seaborne trade of Russia, the Government recognises the importance of immediate measures for the development of the country's mercantile marine. Proposals having this object in view have been put forward by the Ministry of Trade and Industry in a Memorandum accompanying the estimates of that Department for 1917. Concurrently with the re-establishment and expansion of existing lines, vigorous action is recommended in connection with plans for (1) a line from Odessa to London; (2) a line from Baltic ports to Vladivostok; and (3) services forming communications between Russian and foreign ports in Europe with the estuaries of the Siberian rivers Obi and Yenisei. Special importance is attached to the creation of direct lines to America, under the Russian flag, for passenger traffic.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, NOVEMBER 26...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Lieut.-Colonel the Hon. Sir John McCall, "Land Settlement within the Empire."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. (Harben Lectures.) Dr. A. Carrel, "The Treatment of Infected Wounds." (Lecture I.)

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Rev. T. Davis, "The Social Evolution of India."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Maggioro Cav. Filippo de Filippi, "The Geography of the Italian Front."

TUESDAY, NOVEMBER 27...Swiney Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture VII.)

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. (Harben Lectures.) Dr. A. Carrel, "The Treatment of Infected Wounds." (Lecture II.)

University of London, University College, Gower-street, W.C., 5 p.m. Professor S. D. Adshead, "Housing Problems after the War." (Lecture IV.)

WEDNESDAY, NOVEMBER 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Colonel M. O'Gorman, "Aerial Transport."

THURSDAY, NOVEMBER 29...Swiney Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture VIII.)

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. (Harben Lectures.) Dr. A. Carrel, "The Treatment of Infected Wounds." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Professor W. C. F. Anderson, "The Dead Hand in Art, Tradition, Convention and Imitation."

FRIDAY, NOVEMBER 30...Swiney Lecture, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture IX.)

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. (Thomas Hawksley Lecture.) Captain H. R. Sankey, "Heat Engines."

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—November 23, 1917.

No. 3393. NOVEMBER 30, 1917. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers nearly four thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,393. VOL. LXVI.

FRIDAY, NOVEMBER 30, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 3rd, at 4.30 p.m. (Cantor Lecture.) H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, "Progress in the Metallurgy of Copper." (Lecture I.)

WEDNESDAY, DECEMBER 5th, at 4.30 p.m. (Ordinary Meeting.) SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., "Discovery and Invention" (Inaugural "Trueman Wood" Lecture). ALAN A. CAMPBELL SWINTON, F.R.S., Chairman of the Council, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

HOWARD LECTURES.

The Howard Lectures on "The Shortage of the Supply of Non-Phosphoric Iron Ore," by William George Fearnsides, M.A., F.G.S., M.Inst.M.E., Sorby Professor of Geology in the University of Sheffield, have been reprinted from the *Journal*, and the pamphlet (price one shilling) can be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C. 2.

A full list of the Lectures which have been published separately, and are still on sale, can also be obtained on application.

EXAMINATIONS.

The results of the 1917 Examinations have now been published in a pamphlet of 126 pages, folio, which can be obtained at the Society's offices, price 1*s.*, or by post 1*s.* 2*d.*

Copies have been sent to all examination centres.

The results had previously been communicated to all the candidates.

JUVENILE LECTURES.

A course of two lectures, adapted to a juvenile audience, will be delivered on Wednesday afternoons, January 2nd and 9th, 1918, at 3 p.m., by Mr. P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, on "Animal Camouflage."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

"OWEN JONES" PRIZES.

Competitions, under the terms of this Trust, have been held annually from 1878 to 1915 in connection with the National Competition of the Board of Education. This competition not having been held in 1916, the prizes were not awarded, but a special competition was held in 1917.

The Council are now prepared to offer six prizes for designs for (1) Chintzes, and other Stamped, Printed, or Stencilled Textile Materials; (2) Wallpapers; and (3) Tiles.

Each prize will consist of a bound copy of "The Leading Principles in Composition of Ornament of Every Period," from the "Grammar of Ornament," by Owen Jones, and the Society's Bronze Medal.

The competition is limited to students of Schools of Art.

No competitor may send in more than a single design for each of the above-named manufactures, but that design may be accompanied by one or two working drawings or other illustrative sketches.

A sample of manufacture executed from the design may be submitted with, or in substitution for, the original design; but every submitted work must be approved by the master or other authority of the student's school, who must also certify that the design is the work of the student sending it in, and that it has been executed since June, 1917.

No candidate who has already received an Owen Jones prize for any of the above-named manufactures can take part in the competition.

Competing designs must be sent, carriage paid, and labelled "Owen Jones Prize Competition" on the outside, to the Director and Secretary, Victoria and Albert Museum, South Kensington, S.W. (7), between June 24th and June 29th, 1918. They may be delivered by hand on any one of the three days ending June 28th.

The sender must also notify the Secretary of the Royal Society of Arts by post that the design has been sent in, and must enclose stamps or P.O.O. for the return carriage.

No special conditions are laid down as to the size or character of the drawings sent in, but the attention of competitors is drawn to the following remarks of the judges on the competition in 1917:—

"The judges think it desirable that greater stress should be laid by the students' teachers on the necessity for more attention to the technical details required in designs intended for reproduction by printing or in the loom. Very few of the designs sent in had appended to them any explanatory specification, such as is usually required for the guidance of the technical craftsman who has to put the artist's drawing into the shape necessary for reproduction."

The awards will be made by the Council of the Royal Society of Arts on the recommendation of judges appointed by them.

The Council reserve the right of withholding any or all of the prizes offered, and they will be the sole judges in each individual case of the qualifications of a competitor to receive an award.

All possible care will be taken of the designs, but the Council accept no responsibility for injury or loss.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

Wednesday, November 28th, 1917; The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S., Vice-President of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Birnie, Cyril Montague, Japan.
Boyd, John St. Clair (jun.), Belfast.
Campbell, James, Saltburn-by-the-Sea.
Hirst, Stuart A., Leeds.
Humphrey, George Harold, London.
Kaye, Harry, M.Inst.Met., London.
Pitman, Archibald R. C., W.S., Edinburgh.
Roe, Humphrey Verdon, Manchester.
Voight, Howard Edward Latimer, Stanmore, Middlesex.
Warner, Frank Cloudsley ff., London.
Wiblin, Frederick Avent, Plymouth.

[Mr. G. Holt Thomas was prevented by illness from reading the paper on "Aerial Transport after the War," which he was to have given. His place was taken, at very short notice, by Colonel Mervyn O'Gorman, C.B., who, owing to pressure of work, was unable to prepare a paper in time for it to be set up in type and submitted to the Censor before the meeting.

In these circumstances it became impossible to publish the paper in this number of the *Journal*, but the usual report of the meeting will appear in the issue of December 7th.]

COLONIAL SECTION.

A meeting of the Colonial Section was held on Monday, November 26th, 1917; The Right Hon. Walter H. Long, LL.D., F.R.S., M.P., Secretary of State for the Colonies, in the chair.

The Chairman, in opening the meeting, said that during a very long Parliamentary career he had always been profoundly interested in the question of the settlement of citizens from this

part of the Empire in other parts of the Empire. When he first began to take an interest in that question there was a great deal of opposition to anything of the kind. People looked upon the transference of a man's home from the United Kingdom to some distant part of the Empire as a form of exile, and they resented and resisted it. He deprecated any system of compelling or bribing able-bodied citizens of the Empire, who were wanted in the home country, to leave that country. On the other hand, it was not desirable to try to control the wishes and the movements of free citizens, and if men or women desired to transfer their energies and their intelligence and their muscles to another part of the Empire, they should not be prevented from doing so. If they wished to go, everything possible should be done to ensure their leaving this country and entering the land of their choice under the most satisfactory conditions. All the pitfalls that often beset them on the way should be got rid of; their departure from this country should be made easy for them, and their reception on the other side secure, so that they would not fall into temptation and danger, but have a fair start from the beginning. He had personally watched, in more than one part of the Empire, the work done in that way by the Salvation Army, and he had the greatest admiration and gratitude for the service that body had rendered to the Empire by the care they had taken of those people who had gone from this part of the world to other parts of the British Dominions. It was customary to talk of "emigration," but he hoped the time would soon come when that word would be replaced by the word "migration." There was in reality no difference between the movement of a man from Cornwall to Caithness and the movement of a man from the United Kingdom to Australia or Canada or Newfoundland or South Africa, or any other part of the British Empire. He hoped that, whatever changes might be effected, and whatever alterations in our policy might be made, everything would be done to ensure that those who desired to leave the country of their birth, the United Kingdom, should have every opportunity offered to them to go to another part of the same Empire, and there continue the work of Empire-building.

The paper read was—

LAND SETTLEMENT WITHIN THE EMPIRE.

By Lieut.-Col. the Hon. Sir John McCall, M.D., LL.D.,
Agent-General for Tasmania.

The subject of the paper I am about to read is one that demands the early attention of the people of the British Empire. The Empire is large, representing about a quarter of the land of the world, and parts of this are very sparsely populated, while much of it is uninhabited. It contains the bulk of the raw materials required for industries, and if these raw materials are taken in hand by the Governments of the various parts of the Empire where they exist, and are not allowed to drift into the hands of other Empires without a *quid pro quo* being secured to our own Empire, much will be done to maintain a larger population than we had before the commencement of this war which has been forced upon us by Germany —the country which has always been active in getting possession of our raw materials to support their own industrial population.

In addition to our raw materials, our inventions should also be protected primarily for our own people. The Board of Inventions set up during the war should be continued, and when a great invention is made the inventor should be protected and, if necessary, on the recommendation of the Board, the Government of the country should on fair terms stand behind the inventor, assisting him financially and in the development of the industries his invention may make possible.

I trust that the recently appointed Reconstruction Minister (Dr. Addison) may be successful in his office, and that he will make recommendations which can be accepted by the Imperial Government and the people of this country. Here we have, in connection with the manufacture of munitions, large new towns accommodating hundreds of thousands of munition workers, huge plants, machinery, tools, etc. He must see that, at the end of the war, these are not thrown on the scrap heap; the huts must be preserved for permanent dwellings, the machinery and tools must be used in extending factories for the production of manufactured articles, so that we may, in all parts of the Empire, do without the things that are "made in Germany," which have been for many years finding their way over our borders, in most cases without any obstruction. In the Dominions certainly there has been a preference in customs duties in favour of the Mother Country, but the Mother Country has taken millions of pounds' worth of manufactured goods from Germany, while she has maintained what she calls a balance of trade by supplying her in return with coal, the product of a primary industry, and other raw material imported from various Dominions.

If we can persuade the Government to adopt a sound policy after the war, treating our great Empire as we would our own business, developing

it in such a way that every part of it obtains an advantage by the extension of trade, then we shall have reason to thank the Kaiser for consolidating the Empire and demonstrating to the politicians, or should I say statesmen, that it should be their business to look after their own country first. If it is made impossible for Germans to have any political influence in this country by giving big fat subscriptions to party funds, we shall have much to thank the greed of the Kaiser for. I cannot even now see why he wished to crush England; he was getting practically all his own way in our Empire, particularly in this end of it, using our ships for the purpose of pushing his own trade in our far away Dominions, and filling his war chest out of the profits. Had he waited a few years more he would have had peaceable possession. The war, since it had to come, came, thank God, in time, and when we have won it, it will be our business to see that it is not possible for the Kaiser's successor, if he ever has a successor, to give us so much trouble again.

I have indicated something that must be done to create industries and give employment to the workers. I shall not in this paper touch the question of employer and employees any further than to say I am aware that some keen men on both sides are working to try and get their differences settled, for settled they must be if we are to make peaceful progress.

Now I come to the principal purpose of my paper. It is essential for the future well-being of the Empire; it is the settlement of the parts of our Empire which are not already fully settled. Here we have in Britain and Ireland some 45,000,000 of people, while in Canada, Australia, South Africa and New Zealand we have only about 17,000,000 of white people, practically all of our own race. Now, whilst it may be contended that under existing conditions Britain is carrying her full population, it cannot be thought that it has now its maximum population, if the whole Empire is to grow in such a way as to secure trade for the different parts composing it. No doubt, as the population of the different parts of the Empire becomes more balanced, that is to say, when the Dominions jointly possess the same or nearly the same population as the Mother Country, the Imperial Parliament will have to listen to their protest against the gross injustice of what is known as the double income tax, and will have so to impose its taxation as not to prevent a flow of its surplus capital to the parts of the Empire that take its surplus people. At present, if a British subject acquires wealth in Australia, or any other Dominion having an Income Tax Act, and should come to reside in this country, the British Parliament are not satisfied to tax him on the income he brought to this country, but impose their income tax on all his income in the Dominions; as he naturally had to pay an income tax on the income where it was made, he was called on to pay two income taxes on the one income. It should be clear that one income should only pay one income tax. All that has to be decided is, whether the tax should go to the credit of the country where the income is earned, or to the country where the holder of the income resides. Such questions should be considered and settled on sound business lines, and if the Empire is to be developed as one great united Empire, it appears only fair that the income tax should be imposed only on the income in the country where it is earned.

If people in Britain find that their investments in Australia or New Zealand necessitate their paying two income taxes, or three when the State tax is added, it cannot be denied that the Governments are legislating in favour of investments being made in foreign countries where no income tax is imposed. Everything possible must be done to induce our people to settle our own lands, and much can be done if the various sub-nations composing the Empire —together with the Parliament of the United Kingdom—pass legislation in each other's interests, as though it was a part of a great co-partnership. I mean by not insisting on having its "pound of flesh" when such a policy will make for injustice to one part of the Empire, or indeed the whole of it, simply to ensure a little more revenue for itself.

The settlement of our lands has come to be looked upon as one for immediate attention, owing to the fact that so many millions of men have been engaged in this frightful war, and it is believed that a large proportion of them will, after their experience of the advantage of living a free out-of-door life, decide not to go back to their indoor occupations. Further, they have rubbed shoulders with men from the Dominions who are better paid by their home lands, and they will naturally want to go and settle in one of these wealthy or, at any rate, more liberal lands.

The people of the Mother Country now realise the importance of having great loyal populations in the Dominions to help them fight their battles, though perhaps their

importance before the war as great consuming customers was not so generally recognised. As the Dominions have enormous lands to be settled, all parties are in a mind to take up the question in a manner that will be of the greatest advantage to the individual and the Empire. Of course, there are those who believe the lands of the Mother Country can support a much larger agricultural population than at present find a home here, and efforts are being made by legislation to try to increase the number. This is a very wise policy, and everything possible should be done in the interests of this country to settle people on the land and produce more food for home consumption; but there are reasons why this should not be pushed too far, even if it were possible to settle all the people here to get a "hand to mouth" living. We want to hold the Empire outside of these islands, and it is only possible to hope to do this by obtaining sufficient population in the Dominions to prevent other overcrowded countries putting up a claim for some of them for their own people. I do not mean to say that we want these Dominions settled altogether by our own people, and so debar the people of other countries from settling there; but we wish to have a population practically British in every Dominion, with the knowledge that a generation or two will make our foreign settlers British. We must always remember that our whole Empire must have the British spirit, and that "united we stand, divided we fall."

The Imperial Government appointed a committee, of which I was a member, to consider the measures to be taken for settling within the Empire ex-Service men who may desire to emigrate after the war, and the committee, under the presidency of Lord Tennyson, was composed of representative men most of whom had been connected with the question before the war; they examined a large number of witnesses and made an elaborate report last July to the Right Hon. Walter Long, Secretary of State for the Colonies. In this report the committee dealt shortly with what is proposed to be done to encourage men to settle on the lands of the home country, and expressed the view of the Dominions being favourable to the increase of agriculturists in this country, for it is from this class that they prefer to draw their new settlers—not that there is any hope of all their requirements being drawn from such a class. The Home Government have provided for a minimum wage of 25*s*. a week for agricultural labourers, and a guaranteed minimum price for wheat and oats from 1917 to 1922. If this results in grass lands to anything like the 3,000,000 acres it is hoped will be broken up by the plough, it will lead to a much larger number of both skilled and unskilled farm hands being employed after the war than there were employed in 1913. Legislation has been passed empowering the Board of Agriculture to cut up a few thousand acres on which to establish experimental small-holding colonies. The Board have under consideration a scheme to cut up large areas of land if these experimental farms are a success. If these settlements are a success no doubt the United Kingdom will absorb a number of men, but no matter how many men they may absorb, there are not likely to be anything like the number available fully provided for. We must therefore have a central authority to deal with the whole question, either a Minister or a committee or both. In the report I have referred to, it is suggested that a committee be established consisting of five representatives of the Home Government, one to be nominated by each of the following Departments—

- Colonial Office.
- War Office (temporarily).
- Board of Trade.
- Local Government Board.
- Ministry of Labour.

Four to be nominated by—

- Government of the Dominion of Canada.
- Government of the Commonwealth of Australia.
- Government of the Dominion of New Zealand.
- Government of the Union of South Africa.

One of the Agents-General for the Australian States.

One of the Agents-General for the Canadian Provinces.

Five unofficial members, of whom two should be women.

Where the chairman considered it necessary, the Agent-General for any State specially interested should be invited to a meeting of the central authority, and he should act on the committee as a member thereof. Representatives of other parts of the Empire, such as Newfoundland and Rhodesia, or other Departments of the Home Government, should be similarly consulted, and invited to attend meetings and have like voting powers whenever their interests might be involved. The report makes it clear that the committee were of opinion that the organisations which the

Dominions and States Governments maintain, should have the final voice in the selection of ex-Service men to participate in their own special settlement schemes. They further very properly claim that the central authority should be set up before the conclusion of the war, so as to be ready to deal with ex-Service men. The success of the central authority will depend largely on the Minister under whose Department it is placed; whether it be the Secretary of State for the Colonies, or the President of the Board of Trade, it will be necessary that the Minister himself should take a personal interest in the work. My fear is that, having so many Departments under his control, he will not be able to give the attention which is required to the subject, and it should be considered whether it would not be better to create a Minister of Migration to control the whole business of migration within the Empire.

One of the first problems the central committee will have to face will be the difficulty of transport; over a million of ex-Service men will have to be carried back to their homes in different parts of the world; and if the war lasts long enough to allow America fully to participate in it, then the number may be two or three millions. If a large number of ships are not built and held in readiness, the transportation of this enormous number of men will take years to carry out. Therefore the first thing to be done is to push on with shipbuilding in every part of the Empire, and in every part of the world friendly to our Empire. Having the ships available, or rather the knowledge that they will be available, the central authority can take toll of the men desirous of moving to the outposts of Empire, and can set up machinery in the different Dominions, Provinces, States and Colonies to receive and settle them when they land there. If we in the Dominions convey and settle our men, this Mother Country will have to show gratitude to their own men who have helped to save the Empire. I am of opinion that they will have to be helped financially, and others who may go, making room for some of the soldiers to stay in their old homes, should also be helped in the same way. How can they be helped without casting too great a load on the Mother Country? I think it can be done by giving free transport to any part of the Empire they may wish to settle in, and then using the credit of this country to finance co-operative schemes of settlement and public works, the Dominions taking the supervision of the settlements and control of the money until such time as the settlement money has been repaid. The money expended on public works should be allowed to remain as a part of the Public Debt of the Dominions or States. It is true that this would require a large amount of money to be raised on loan; however, if it means raising as much as the cost of the war for a year—about two thousand million pounds—we shall have a good return for it; it will not go off in smoke and shell, but it will settle and secure strength for the Empire, giving a good asset for every penny expended and building up an Empire so strong in "man-power" that even should Germany make satisfactory progress she will never dare to make war on us again.

Every Dominion, Province and State would be invited to say what it will do—that is to say, how many co-operative bodies of men it could settle within its own borders, providing the money was made available for construction of railways, roads, etc., together with the cash to finance the settlers, the first amount being advanced to the States and Provinces to remain a part of their Public Debt, the second to be advanced to the local Governments for the use of the settlers, to be repaid by them over a term of years.

In the past, settlers have in many British Colonies had to fight with timbered country, which it has taken them practically a lifetime to subdue and fit for the plough; but under a proper co-operative system with capital, an up-to-date plant could be provided to saw up suitable timber, to pull up stumps and shrubs, to erect butter, cheese and bacon factories, these factories to be worked on co-operative lines as is now the general practice in Australia. With other lands, such as the Mallee country, a different plant would have to be provided and larger areas of land secured to each settler.

Again, other areas would require drains, etc., for irrigation, and these blocks according to their location and use would be very much smaller, I mean for the individual settler. Wheat land would, as a rule, require larger areas than what are known as mixed farms, these again being larger than plots of 20 acres or so for fruit-growing. In each of these settlements a piece of land from 200 to 300 acres centrally situated should be reserved for a town which would take form as soon as the land was even partially settled; the general store, the factories before mentioned, the school, blacksmith's shop and bootmaker, etc., would be there. Soon there would follow the branch

bank, chemist, etc. All these would give a value to the land in the town, which if rented and not sold would secure a handsome return for the benefit of the whole of the settlers. Mr. Chomley, of *The British Australasian*, advocated a scheme much on these lines before a Royal Commission in Victoria some years ago, and I have asked him to be present to-day to speak in any discussion that may take place when I have read my paper. Allowing that the most expensive scheme, that is to say, the one dealing with the settlement of a hundred people with families on a hundred farms, might need a capital of £50,000, the men taking the lots would have to work at a rate of pay that would permit them to live in comfort, knowing that the difference between the wage they received and the regular rate of pay would ultimately come back to them in securing the farm at a lower cost, and would be a guarantee of their *bona fides* to the Government advancing the capital. I am not prepared to submit a balance-sheet, but would point out that at the end of three or four years the farms should be sufficiently improved for each man to take over his farm and work it on his own account, the town land and the factories continuing to be owned on a co-operative basis. The clearing machinery could be sold and the amount of purchase money deducted from the debt, and the balance divided by the number of settlers would give the mortgage each farm would have to carry, the owners having the option of paying it off if in a position to do so, or paying over a term of years an annual amount sufficient to pay interest and redeem the whole debt on the property. Of course, conditions would have to be made to permit men who became possessed of sufficient money to buy a cleared or larger estate withdrawing from the scheme on equitable lines, to sell, and in case of death to will to others. Indeed, everything should be so arranged that honest workers should be encouraged to join and remain in such settlement schemes, and provision would have to be made for the expulsion of shirkers.

The Colonial Governments would appoint managers from qualified agriculturists, horticulturists, etc., to work with a committee of the settlers elected annually by the whole settlement. I feel confident that if these suggestions are taken up and acted upon, a workable scheme can be secured.

The money must be found by the Imperial Government, just as it was for land purchase in Ireland; it cannot be lost so far as the Dominion or State Government is concerned; it will really only be a loan of the Mother Country's credit, and so far as the loan to settlers is concerned, they will have the security built up by the lower rate of pay the men receive who are going to buy the land. When the Imperial Government adopt this or some other scheme with as fair a promise of success, they will have done their duty to the men able to go on the land, who have done so much in their time to preserve the British Empire for future generations.

[Owing to Mr. Walter Long having to return to the House of Commons for a short time, the chair was taken, during the reading of the paper, by the Hon. Sir Thomas Mackenzie, K.C.M.G., High Commissioner for New Zealand.]

DISCUSSION.

The Hon. Sir Thomas Mackenzie thought that the paper dealt in a practical manner with an important and far-reaching subject. The question of the settlement of our people upon the lands of the Empire must engage the attention of statesmen of the Old Country in conjunction with that of the statesmen overseas. The Dominions must be provided with a sufficient population; or other countries might contest the right of the British people to possess such vast territories unused. He agreed with the author that it ought to be largely British settlement. If we had our own people in our own lands we should have a loyal and patriotic people, who would be prepared to stand by us in adversity and to share in our prosperity when it came. He thought the question of the preservation of child life in this country ought to be taken in hand at once, for if the child life that might be saved here was preserved and trained it would furnish as large a population as our overseas communities could properly absorb. It seemed to him that there was great need for the training of the men who purposed going abroad. It was no use sending a lot of ex-soldiers or other men to the overseas Dominions unless they were first trained in the industries that they were likely to take up on the other side. Any scheme for assisting migration from this country overseas ought to be coupled with a system of training to some extent. For many years he had been the Minister in charge of a Land Settlement Department in New Zealand, which borrowed sums of money to re-purchase estates and finance the men afterwards. Vast areas, amounting to over one and a half million acres of land, had been re-purchased from large landowners, and over six thousand new families had been settled on the land; then there followed the stores and chemists' shops and banks and prosperous communities. The Land Settlement Department had borrowed £16,356,000 to help the settlers to clear

their lands and make their settlement a success. That scheme had been so successful that those settlers had repaid £8,256,000, more than half of the total amount that had been borrowed, and thousands of them had made their holdings their own. They were also assisted in erecting factories and shipping their produce across the ocean.

THE HON. SIR JOHN W. TAVERNER, K.C.M.G., agreed with Mr. Long that British people should have the right to make their home within any part of the Empire they chose. The war had consolidated the British people to the extent that those in the Colonies were now allowed to express their opinions on matters affecting the interests of the Empire; and men like Mr. Hughes and other leading public men could tell the Mother Country what her duty was in connection with promoting the best interests of the Empire. He agreed with the author that the Tennyson report was a very good report. The first part of that report was an indictment against the British Government for not doing its duty, and the remaining part informed the people of this country what the overseas Dominions were doing for land settlement. The recommendations of the Tennyson Committee were sound and good, but any policy of migration to the overseas countries should be carried out by the co-operation of the home Government and the overseas Governments, and great care should be taken to see that there was no "dumping" of men on the overseas Dominions. It must be remembered that those Dominions would have their own ex-Service men to deal with, and he thought it would be nearly two years after the conclusion of the war before the overseas countries could get all their men back and deal with the question of their own ex-Service men. After that they would do what they could to co-operate with the Mother Country in dealing with her ex-Service men. In July of 1916 Sir Douglas Haig polled 97,000 men as to their wishes in connection with land settlement, and the result of that poll was that 17,000 men expressed their desire to go upon the land should they return safely after the war. That meant that, taking 5,000,000 men as a basis, 875,000 would have to be provided for upon the land, whereas the British Government had only made arrangements to provide for 300. Thanks to the organised Labour Party in this country, the industrial section of Service men had obtained from the Government a promise that their rights would be preserved after the war, and the Government should give ex-Service men who did not belong to that section an opportunity of making a home on the land in the Mother Country. He would like to give every credit to Mr. Prothero, Sir Richard Winfrey, and Sir Arthur Lee, for the excellent work they had done in that connection. Owing to their efforts, 45,000 ex-Service men were now working upon the land, but nothing had been done by the Government to ensure that those men would be able to make a home in the future within the Mother Country.

THE HON. J. G. JENKINS expressed his great appreciation of the paper, which dealt with a subject in which he had taken the deepest interest for some time. He had been a member of the Committee set up by Earl Grey in connection with the Royal Colonial Institute, and that Committee's work had a good deal to do with the appointment of the Tennyson Committee. It was much more difficult in Great Britain and Ireland to obtain land for settlers than it was in the Dominions, and he believed that the present Government fully recognised that, and that legislation would later on be adopted by which readier access could be obtained to larger tracts of land for the settlement of men who desired to work upon the land. The question of colonisation must be considered from a national citizenship point of view. The time had gone by when people in New Zealand and Canada and Newfoundland were considered foreigners; they had just as much right to be considered members of the British Empire as those who were born and lived in the Mother Country. With reference to Sir Thomas Mackenzie's remark that if the right kind of people were settled on the land, nothing would be lost by re-purchasing and selling land to those people, the Government of South Australia had spent millions of money in re-purchasing and settling men on the land, and had never lost a penny by those schemes. He would also like to emphasise the statement made by Sir Thomas Mackenzie that it was generally useless to put people on the land if they had no knowledge of the work they would have to do. Sometimes men who had never worked on the land before managed quite well, but the majority of them needed a certain amount of instruction in agriculture in the country in which they intended to settle. Such instruction was given at agricultural colleges in Australia, Canada, New Zealand and South Africa, and he thought such colleges might also be established in the Mother Country. He hoped that the Government would appoint a permanent committee on the lines suggested by the Tennyson Committee, in order to arrive at a basis of agreement between the Dominions and the home Government as soon as possible, so that after the war the problem of settling ex-Service men on the land could be properly dealt with. It did not matter if millions had to be borrowed for that purpose, because the undeveloped resources of the Empire would return an adequate interest on any amount of money that was expended in that direction. There were millions of acres in the overseas Dominions waiting to be cultivated, and if a uniform scheme of migration was arranged between the home Government and the Governments of the Dominions, it would result in permanent benefit to the British Empire.

COMMISSIONER D. C. LAMB, Salvation Army, said that the author had mentioned what he called an expensive scheme of settling one hundred people with families on a hundred farms at a capital expenditure of £50,000,

i.e. £500 per family. When he took what the British Government had done he found it worked out at £900 per family; but no man would have a better chance in the north of Scotland, say, than in Western Canada. He felt rather doubtful as to how far settlement in the home country should be proceeded with. The author had spoken in his paper of the increased acreage that was going to be brought under the plough; of guaranteed wages and of a guaranteed price for wheat and oats; but he was not sure that there would be more people on the land even then. With improved machinery so many people would not be required. What was really wanted was more production. With regard to the need for training men for work on the land, that would not be so necessary in the future as it had been in the past, because the ex-Service men would be found to be capable of adapting themselves quickly to new conditions. Statistics published last week showed that in a certain part of the British Empire the percentage of British and British-born citizens was only 60 per cent. of the population. That must be altered in the future, but, as had been already said, there must be no "dumping" of men on the Colonies. The Salvation Army long ago saw the evils of such "dumping," and organised emigration in such a way as to prevent that evil. They selected people from amongst those who wanted to emigrate, tested them in certain ways, secured their passages and arranged for them to be met on their arrival, and did everything possible to prevent the men from feeling that they were being exiled. They went straight from the ship to the work that had been found for them, and the Salvation Army insured them against accident, loss of luggage and unemployment. If the Salvation Army could do all that, surely the State, if it took the work in hand, could multiply it, and in that way there could be no possibility of failure.

Mr. C. H. Chomley said he had had some practical experience as a settler on the land in Australia, and had himself ploughed many acres of bush land. He was quite sure that in Australia or any other Colony there was hardly a single man who, under proper direction, even without experience, was not perfectly capable of earning his keep and a moderate wage from the very beginning. Men under direction and discipline and receiving wages, as a rule, could be made to do good work; and, on the other hand, men who had the incentive of owning their own property would also do good work. In his scheme, which the author had mentioned, he had attempted to combine those two things. Roughly, his scheme was that a Government—or preferably, from his point of view, an association of private individuals—should take over a certain large area of, say, 10,000 acres of bush land in the Dominions, which had all the elements of fertility, but which, under individual settlement, could not be properly developed, because it was far from a railway and its amount of timber was greater than individual settlers could cope with. He proposed that the Government or association should equip that area of land with sufficient capital to provide saw-milling plant, which would convert the timber from being an incubus to the individual into a great asset to the community. The timber would be cut into lengths, stored and seasoned, and after three or four years it would be sent to a railway, and in many cases that timber would more than pay the whole of the cost of clearing the land. When cleared, those 10,000 acres would be divided up into lots of 100 acres, so that 100 men would be settled on them. He suggested that the company, or the people who provided the capital, should pay those men a living wage for a term of three years, say £1 a week, and establish stores at which they could buy everything they required at the lowest possible cost; clear the land, divide it, put fences on it and build houses, and, at the end of the three years the land should be given to the men in the form of 100 farms. They should be debited with the money spent upon the plant and upon their wages, less the cost of the timber which had been sold and the sale of the plant which had been used for clearing the land. In many cases, instead of there being a debit to the community, there would be found to be a credit at the end. Even assuming that there was no credit side to it at all, there would be a hundred families in a settled community entering upon cleared farms in three years, having been taught to manage the land themselves. He suggested that when those 10,000 acres of bush land were taken up in some central position, there should be reserved an amount adequate for a township, say, 300 acres, and that those 300 acres should be the property of the community, a half-share going to the people who had provided the capital, and a half-share going to the settlers who formed the community. A hundred good farms would form the nucleus of a very flourishing settlement, and in time to come those township lands would be very valuable, and their sale, or the rents from them, would go a long way towards recouping the capitalists for the money they had expended. He was convinced that if the proper land was selected his scheme might be repeated over and over again in Australia, New Zealand, Canada, and even the Mother Country, the people who supplied the capital obtaining an interest of about 5 per cent. as well as a half-share in the value of the town lands.

Mr. H. E. Easton (Hon. Secretary, British Empire Land Settlement Propaganda League) thought that thanks were due to the Government and to Mr. Long for the able work they had already done. Sir Richard Winfrey had made a proposal to the Government to take over one and a half million acres of land for cultivation by ex-Service men. He hoped those proposals would

meet with the necessary support, and that the Government would not hesitate to give Sir Richard Winfrey and his Department (the Board of Agriculture) the legislative power they wanted. The British Immigration League had received many letters from officers and men at the Front saying, "Is the only reward for our fighting to be told by the British Government that we have got to migrate from the very land that we have fought for?" It would not do to weaken the heart of the Empire too much, but if the overseas Dominions were not going to be replenished with British settlers, they might have to look to the nations we were to-day at war with for their future supply of population. Mr. Lloyd George, in answering a deputation in March last, said, referring to settlement on the land after the war, that not a day ought to be lost, because, if it was, the opportunity would pass away. A good many days had already been lost, and, in spite of the Prime Minister's warning, all that the Government had done was to make arrangements for the settlement on the land of less than three hundred men.

Mr. Henry Samuel said he happened to be the representative for the overseas Dominions at the Small Holdings Congress which was held at the Crystal Palace under the Presidency of Lord Carrington (now Marquess of Lincolnshire), and he hoped the Government would not attempt to develop land in this country under a small holdings scheme. No ex-soldier would ever be able to exist under that system. The large amount of capital required to settle the men on the land should be provided by private enterprise, probably under some such scheme as that which Lord Cromer introduced to develop Egypt, namely, by the Government guaranteeing a minimum dividend.

Mr. Octavius C. Beale then proposed a vote of thanks to Sir John McCall for his paper.

Major-General the Hon. Sir Newton J. Moore, K.C.M.G. (late Agent-General for Western Australia), in seconding the resolution, said that some of the suggestions put forward in the paper had already been carried out in Australia. He hoped the new committee would be very careful to appoint practical men who could dissect the various proposals that were made. The land first had to be classified—the land in Australia, for instance, being very "patchy," and a chessboard scheme not being practical politics there. The question of transport facilities also had to be considered.

The resolution was carried unanimously.

On behalf of the Council, Lord Blyth, Chairman of the Colonial Section Committee, thanked Mr. Long for his kindness in taking the chair at considerable personal inconvenience.

The Chairman (Mr. Walter Long), in reply, appealed to those who criticised the Government for not doing more in the way of settling men upon the land to bear in mind that at the present time the only men who were released from military service were men suffering from repeated wounds or serious deterioration of health, and those were not the men who could begin a great scheme of the kind in question. It was not right to blame the Government because only a limited number of men had been settled on the land. He was in general agreement with the paper, and also with the remarks of some of the speakers, especially Commissioner Lamb. In connection with the settlement of men on the land, the motto *festina lente* should be remembered, as there was no question about which it was so easy to make mistakes and so difficult to redress them. Wisely and well thought out it might bring benefit both to the Empire and to the men themselves, but hurriedly undertaken it might bring great trouble upon the Empire and greater disaster upon the men. Any seeming delay on the part of the Government was due neither to want of will nor to want of energy, but solely to the desire to proceed with due caution, and to consider carefully the steps to be taken before they were beyond the power of being retraced.

The meeting then terminated.

Sir John McCall, in reply to the discussion, writes:—In returning thanks for the vote, I should like to say that my object in reading the paper was to get a scheme discussed, and to render help to the Government in the enormous task before them. Further, I wish to make it clear that the Dominions and States are doing their full part in looking after their own men, and that they cannot be expected to provide for the soldiers belonging to the Mother Country as well. I had no desire to criticise the Imperial Government, and am sorry the discussion in part took that turn: as a matter of fact, I do not know what they have done beyond obtaining the Tennyson Committee's report. I am anxious to impress upon the Government the importance of providing passenger ships, without which no scheme will be possible, and, secondly, that they must finance any scheme for their own men if it is to have a chance of success.

ENGINEERING NOTES.

The Quebec Bridge and the Catskill Aqueduct.—The technical press has given ample details of two recent engineering undertakings. The first is the account of the practical completion of the Quebec Bridge which took place on September 20th last, after the failure of the bridge in 1907 owing to faulty design, and a partial mishap of last year, due to what may be properly termed accident. We owe the design

and erection of this greatest of bridges to the ability and courage of many brains, and it is well to remember that the profession has triumphed over its many difficulties and disappointments. The other enterprise, the Catskill Aqueduct, finished in the middle of October, will be hardly less important. After twelve years' co-operation with the other water supplies which have been in operation for years, 500,000,000 more gallons of water per day can be brought to New York to-day. The work cost £22,000,000. The New York Board of Water Supply was organised in 1905, and at once selected Mr. J. Waldo Smith as their engineer-in-chief. The works extend from the Schohate and the Esopos gathering ground, 600 square miles in all, and lead to the Hudson River, which is crossed by a subaqueous tunnel. These two undertakings, were they not greatly overshadowed by the war cloud, would be classed as engineering works of the first magnitude.

The Dikes of Ostfriesland.—The proposal, initiated by the *Graphic*, to flood the country containing the ports of Emden and Wilhelmshaven by breaking down with bombs the earthen embankments which shut out the sea, is a novel instance of aerial strategy. We presume that the drowning of the civil inhabitants of the country, which the proposal involves, is not intended. The fens (forty-two miles east to west) are protected by dikes 20 ft. to 30 ft. in height, and to show the injuries done to the fens in the past, instances are given of the inundations of 1218, 1511, 1717, and 1825, in which many of the inhabitants were drowned. Bomb attacks by aeroplanes are mentioned as a means of carrying out this proposal.

Brisbane Water-supply Reservoir.—A concrete dam of gravity section with rock plums, faced with reinforced steel rods, 125 ft. high from foundation to top, designed to impound about 7,000,000,000 U.S. gallons of water, was officially put in use in December 1916 by the Metropolitan Water Board of Brisbane, Queensland, Australia. The structure, according to the *Engineering News Record* of New York, is known as the Cabbage Tree Reservoir dam, and is a part of the waterworks system of Brisbane and its suburbs, supplying a population of about 158,000 at the close of 1916. The main supply is taken from the Brisbane River, by means of a pumping-station about twenty miles from the city. The new dam is located on Cabbage Tree Creek, a tributary of the Brisbane River. The dam is five and a half miles from the pumping-station, with which it will be connected by a concrete conduit. The reservoir has an area of about 700 acres and a catchment area of twenty-eight square miles. The dam rests on blue quartzite, which was found at a depth of 15 ft. below the creek bed. The dam proper is 580 ft. long, and beyond it is a spillway 160 ft. in length. The main construction quantities were: Excavation, 33,222 cubic yards; extra excavation, below assumed bottom, 5,859 cubic yards; spillway excavation, 64,500 cubic yards; cyclopean concrete, 58,400 cubic yards. The rainfall in and near Brisbane is intermittent. For long periods no rain falls, but periodically there are downpours. The longest known period of drought was in 1915, when for eight weeks the Brisbane River was dry. When full, and after allowing for evaporation, the new reservoir will give a supply of 15,000,000 U.S. gallons a day for 300 days, or with greater economy for a longer period.

Continuous Current by Turbine.—The practice of generating continuous current by the use of turbo-alternators, feeding into rotary converters, is rapidly extending. The *Daily Telegraph* says that in a typical plant of this character, which has recently been installed in an important engineering works, there is to be noted a 1,500 k.w. "Witton" turbo-alternator, running at a speed of 3,000 revolutions per minute, and generating six-phase alternating current, which is delivered to two 750 k.w. "Witton" rotary converters, running at 600 revolutions per minute, and generating continuous current at 460 volts. The installation has proved completely satisfactory, and has again demonstrated the utility of this method of generating continuous current, which enables the turbine to be run at a high speed of 3,000 revolutions per minute, so that the highest efficiency is attained, while at the same time the continuous current commutators on the converters can be designed with a peripheral speed consistent with satisfactory working. Providing an interesting contrast to the above-mentioned plant, there is also to be seen in the same works a 750 k.w. "Witton" continuous current turbo-generator set, which has now been running for over ten years. This type of machine is now superseded for the generation of continuous current by the combination described. Other authorities favour the method of driving the continuous current generator through reduction gearing.

Italian State Railway Electrification.—M. Lucien Pahin contributes an article in *L'Industrie Électrique* on the electrification of the Italian State Railway from Bussoleno to Modana. This railway comprises two sections. One extends from Bussoleno to Bardonecchia, about twenty-five miles. Here there are declivities averaging 1 in 20, and many tunnels and artificial structures where steam operation creates intolerable conditions. The other section extends from Bardonecchia to Modana, on Mont Cenis. It is

11·8 miles in length, and includes the Col de Frejus tunnel 45,000 ft. long, which is ventilated artificially. The growth of traffic had caused many difficulties in the operation of this railway by steam, all of which have been overcome by the adoption of electricity with the increased capacity, regularity and speed thereby obtained. Power is to be supplied eventually by hydro-electric installations in the valleys of the Alps, contracts having meanwhile been entered into with the municipality of Turin for three-phase energy at 55,000 volts 50 cycles, produced by a 3,500 kva. turbo-alternator—this to be supplied by energy from other sources.

Coal in Queensland.—The engineers of the Queensland Mines Department report that they have proved over an area of one square mile of the Bowen coalfield, deposits representing 22,000,000 tons of coal. It is certain, therefore, that we may look for important developments in this region in the near future. Electrolytic works at Bowen, mines and smelting works at Cloncurry, may become large users of power, while Bowen and Townsville are the nearest Australian ports to the Panama Canal. Ships sailing from more southern ports of Australia for the Panama Canal must coal at one or other of these points. Crown lands of about 500,000 acres in extent, are available for settlement at Bowen.

Removing Rust by Electrolysis.—An electrolytic process of deoxidisation, says the *Scientific American*, has been patented in the United States. The object to be treated is made the cathode in an electrolyte containing phosphoric acid. In addition to its normal function of carrying the current, this acid acts as a solvent upon rust without attacking the steal or iron body beneath. It is in this last detail that its chief availability lies, since nitric, sulphuric, or hydrochloric acid would not display such moderation. Finally, the phosphoric acid is beneficial in preventing subsequent further rusting. The electrolyte is made by adding ten parts of phosphoric acid to ninety parts of water, or adding 10 per cent. of the acid to a 10 per cent. solution of sodium phosphate. A temperature of between 50° and 70° C. is recommended.

OBITUARY.

WILLIAM CHARLES KNIGHT CLOWES. — Mr. William Charles Knight Clowes died on Monday, the 19th inst., at his house in Cranley Gardens, South Kensington. He was born in July, 1838, and was therefore in his eightieth year at the time of his death. He was the eldest son of George Clowes, the son of the founder of the well-known printing firm of William Clowes & Sons. Mr. Clowes was educated at Eton and Christchurch, Oxford, and after leaving the University he joined his father's firm. In the early days of the Volunteer movement he raised a company among the employees of the firm, and of this he became the Captain. On his father's death the principal management of the printing business, in which he had previously taken an active part, came into his hands; and, later on, when the firm was made into a limited company, he became its Chairman. The Beccles printing business, founded separately by him, together with his cousin, at an earlier date, was at the same time amalgamated with the London house.

At an early date in the history of their business Messrs. Clowes acquired a high reputation for fine and beautiful printing. Their productions were many and various, and it may be said that all the more important of their undertakings were brought out under the direct personal superintendence, first of the grandfather, then of the father, and afterwards of the son. George Clowes took a prominent part in the production of the catalogues and other publications of the 1851 Exhibition. The Jury Reports of the 1862 Exhibition (issued by the Society of Arts) were printed by Messrs. Clowes, to whom were also entrusted the printing of all (or nearly all) the publications issued in connection with all the succeeding great International Exhibitions, down to that of Chicago in 1893. The "Law Reports" were established by the joint efforts of father and son, the firm guaranteeing the necessary funds. The firm made a speciality of printing in foreign languages, and by the purchase of the large stock of foreign type accumulated by Messrs. Gilbert & Rivington, they were enabled to extend this branch of their business, and they would now undertake to set up and print manuscripts in any language which possessed an alphabet. The reputation of his firm naturally led to Mr. W. C. Knight Clowes taking a very prominent part in all matters connected with the printing trade, a part for which his personal character and capacity amply qualified him. He was the founder of the London Master Printers' Association, and the valuable work he did as Chairman of that Association was recognised by his colleagues, who presented him with a service of silver plate on his retirement. Latterly, failing health and advancing years compelled him to take a less active share in the management of his firm's business, and he resigned the Chairmanship in 1915.

He was elected a Member of the Society in 1885, following the example of his father, who had been a Member from 1851 till his death in 1886. He was twice elected on the Council, in 1905 and 1909. He was a very old member of the Athenæum and the Oxford and Cambridge Clubs, having nearly completed fifty years' membership of the former when he resigned last year. He was well known to a large circle of friends, who appreciated his high character and his kindly, genial nature, and who in years gone by frequently enjoyed his generous and cordial hospitality.

WILSON NOBLE.—Mr. Wilson Noble, who had been a member of the Royal Society of Arts since 1888, died on October 31st. Born in 1854, he was educated at Eton and Trinity College, Cambridge, of which he was a Fellow. From 1886 to 1895 he sat as Conservative M.P. for Hastings. He devoted a great deal of time to electrical investigations, especially in connection with X-rays, and did some excellent work in the early days of the medical applications of radiography. He was President of the Röntgen Society of London in 1899-1900, and wrote some important papers on X-ray technique.

ALEXANDER MACOMB CHANCE.—Mr. Alexander M. Chance died at Torquay on the 22nd inst., at the age of seventy-three. He was for many years associated with the management of Messrs. Chance Brothers & Co., chemical manufacturers, of Oldbury. Generous and public-spirited, he spent large sums on schemes for the benefit of his workpeople and on charitable works. He succeeded the late Mr. Arthur Chamberlain as Chairman of the Birmingham Licensing Committee.

He was elected a member of the Royal Society of Arts in 1882, and in the same year he read a paper on "The Recovery of Sulphur from Alkali Waste (Schaffner and Helbig's Process): a Record of Recent Results," for which he received the Society's silver medal.

GENERAL NOTES.

SUBSTITUTE FOR BRAN. — *Il Sole* (Milan) for September 14th publishes a notice regarding a new industry in Liguria, which has arisen out of the discovery of a substitute for bran. The substitute, it is said, is manufactured from materials which, before the war, were practically wasted. The main constituent of the substitute is sugar obtained from the fruit of a species of palm which abounds on the Ligurian coast, and which has hitherto been considered useless. By a special process this fruit has been made to yield as much as 40 per cent. of sugar, which is added to dried figs, rice husks, dregs of pressed grapes, raisin stones, acorn husks, young twigs and tomato parings, after the whole has been subjected to disintegration, pulverisation and kneading. *Il Sole* gives an analysis of the bran substitute thus produced, and points out that the high percentage of sugar which it contains renders it a suitable food for horses. A factory is stated to have been established at Loano capable of producing 200 metric quintals (nearly 20 tons) of the bran substitute per day.

INDUSTRIAL FATIGUE. — In the course of a Chadwick Lecture on "Fatigue and the Worker —Causes, Effects, and Reliefs," Professor Henry J. Spooner said that the success of women in operations hitherto regarded as men's tasks had been remarkable, and a distinguished engineer had declared his conviction that, given two more years of war, he could build a battleship, from keel to aerial, entirely by woman labour. The nation's call upon the industrial army to work the longest hours possible had been nobly and patriotically responded to, but observation and experience had shown that when the working hours were too long, fatigue toxins developed and weariness reduced exhilaration of effort, increased nerve-strain, and induced breakdown. The gross output was increased when long hours were reduced, so the problem to be solved was what length of working-day was, on the whole, most economical and best for the worker. The lecturer's investigations had tended to prove that the abolition of Sunday work and the shortening of working hours, with more general adoption of short intervals of rest, varying in length and frequency with the work done, would still further increase output, the other conditions remaining the same, but there were obvious difficulties in arranging this in practice. Holiday fatigue first led to a falling-off in production, but the recuperative effects of a holiday were soon operative, with consequent increase in production. Methods of preventing waste of time and effort in work were described, which in cloth-folding had reduced motions of the worker from 20 and 30 to 10 and 12, and had enabled a typist at a contest in New York to defeat the international champion by writing the unheard-of gross of 147 words per minute for the entire contest, and 137 words net, or five words per minute more than anything that had previously been done. The economy of movement gained by assembling small machines on the Gilbreth principle, with specially-arranged packets of the component parts, was also shown.

ELECTRIC TRUCK FOR WHARF WORK AT WELLINGTON HARBOUR.—H.M. Trade Commissioner in New Zealand has forwarded particulars of a series of tests carried out at Wellington with a new electric storage battery truck, intended for use on the waterfront. The truck is of American manufacture, and is the first of its kind seen in New Zealand. It is about 8 ft. long and 3 ft. wide, and runs on four small wheels placed underneath the body. The batteries, of which there are forty-two of the Edison type, are carried under the platform, and thus do not take up any carrying space. The batteries are capable of running the truck for a full working day. The driver stands on two divided steps at the end of the vehicle. One of these steps switches the current on when it is desired to start the truck, and the other controls the brake. The steering, which is done on all four wheels, is effected by a tiller, and the electric motor is controlled by a small lever placed at one side of the platform. The capacity of the truck itself is 4,000 lb., and the price is about £500.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

December 5.—Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., "Discovery and Invention" (Inaugural "Trueman Wood" Lecture). Alan A. Campbell Swinton, F.R.S., Chairman of the Council, will preside.

December 12.—Lord Charnwood, "Technical Training for Disabled Soldiers and Sailors."

December 19.—Professor J. Wemyss Anderson, M.Inst.C.E., M.I.Mech.E., Dean of the Faculty of Engineering and Lecturer in Refrigeration, University of Liverpool, "Science and the Cold Storage Industry." The Hon. Sir Thomas Mackenzie, K.C.M.G., High Commissioner for New Zealand, will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m.:—

December 13.—D. T. Chadwick, I.C.S., "The Trade of India with Russia, France, and Italy." The Right Hon. Lord Islington, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

Cantor Lectures.

Monday afternoons, at 4.30 p.m.:—

H. C. H. Carpenter, M.A., Ph.D., M.Inst. M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology. "Progress in the Metallurgy of Copper." Three Lectures.

December 3, 10, 17.

The arrangements for the meetings after Christmas were announced last week.

MEETINGS FOR THE ENSUING WEEK.

Monday, December 3...ROYAL SOCIETY OF ARTS, John street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor H. C. H. Carpenter, "Progress in the Metallurgy of Copper." (Lecture I.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Mr. W. Dale, "Prehistoric Man: his Antiquity and Characteristics."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 6 p.m. Annual General Meeting.

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

Tuesday, December 4...Swiney Lecture, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture X.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. G. B. Walker, "Recent Developments in By-product Coking."

University of London, University College, Gower-street, W.C., 5 p.m. Professor S. D. Adshead, "Housing Problems after the War." (Lecture V.)

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Miss A. M. Anderson, "Women Workers and the Health of the Nation."

Chemical Industry, Society of (London Section), at the Chemical Society, Burlington House, W., 8 p.m. Professor H. Louis, "The Economics of Coal Production."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C. Mr. A. K. Sabin, "Ecclesiastical Wall Paintings in England from the XIIIth to the XVIth Centuries."

London Chamber of Commerce, Oxford-court, Cannon-street, E.C., 2.30 p.m. Lord D'Abernon, "Improved Sea Communication."

Wednesday, December 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir Dugald Clerk, "Discovery and Invention." (Inaugural "Trueman Wood" Lecture.)

Aëronautical Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m.

Geological Society, Burlington House, W., 5.30 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 5 p.m. 1. Messrs. P. J. Fryer and F. E. Weston, "The Valenta Number as a discriminative Test for Oils and Fats." 2. Mr. H. E. Cox, "The Composition of Sharps and Bran." 3. Mr. W. T. Burgess, "Notes on Porcelain." 4. Mr. E. R. Dovey, "Note on the Colorimetric Estimation of Iron."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Mr. A. H. Thompson, "Some Notes on the Lesser Colleges of Secular Canons in England."

Geological Society, Burlington House, Piccadilly, W., 5.30 p.m. Messrs. E. Heron-Allen and J. E. Barnard, "Demonstration on the Application of X-Rays to the Determination of the Internal Structure of Microscopic Fossils, especially with regard to the Dimorphism of the Nummulites."

Thursday, December 6...Swiney Lecture, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture XI.)

Chemical Society, Burlington House, W., 8 p.m. Dr. F. L. Pyman, "The Relation between Chemical Constitution and Physiological Action."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Captain H. R. Hall "The Excavation of an Egyptian Temple (the Temple of Menhihotepat Deir-el-Behari)."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. W. A. Gillott, "Electrical Cooking as applied to large Kitchens."

British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. Major Sir Filippo de Filippi, "Italy's Protection of Art Treasures and Monuments during the War."

Friday, December 7...Swiney Lecture, at the Royal Society of Arts, John-street, Adelphi, W.C., 5.30 p.m. Professor J. S. Flett, "The Mineral Resources of the British Empire." (Lecture XII.)

Philological Society, University College, W.C., 8 p.m. Professor W. Rippmann, "Simplified Spelling."

JOURNAL
OF THE
ROYAL SOCIETY
OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers nearly four thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,394. VOL. LXVI.

FRIDAY, DECEMBER 7, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 10th, at 4.30 p.m. (Cantor Lecture.) H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, "Progress in the Metallurgy of Copper." (Lecture II.)

WEDNESDAY, DECEMBER 12th, at 4.30 p.m. (Ordinary Meeting.) LORD CHARNWOOD. "Technical Training for Disabled Soldiers and Sailors." SURGEON-GENERAL SIR ALFRED KEOGH, G.C.B., M.D., F.R.C.P., Director-General of Medical Services, will preside.

THURSDAY, DECEMBER 13th, at 4.30 p.m. (Indian Section.) D. T. CHADWICK, I.C.S., "The Trade of India with Russia, France, and Italy." The RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, December 3rd, Mr. H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, delivered the first lecture of his course on "Progress in the Metallurgy of Copper."

The lectures will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

A course of two lectures, adapted to a juvenile audience, will be delivered on Wednesday afternoons, January 2nd and 9th, 1918, at 3 p.m., by Mr. P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, on "Animal Camouflage."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

SECOND ORDINARY MEETING.

WEDNESDAY, NOVEMBER 28th, 1917; THE HON. SIR CHARLES ALGERNON PARSONS, K.C.B., LL.D., D.Sc., F.R.S., Vice-President of the Society, in the chair.

THE CHAIRMAN, in opening the meeting, said it might be interesting to recall the position of aeronautics in the year 1887, thirty years ago, when he was personally very much interested in the subject. He read the works of Langley, the American experimenter, and the works of most other experimenters at that date, and he studied models of aeroplanes and helicopters, himself making a helicopter which lifted itself 20 or 30 ft. from the ground by its own power, by means of a steam engine. When the same helicopter was mounted on planes, like the modern aeroplane, it flew for several hundred yards. About two or three years before that, Langley had made a small flying machine of about 10 lb. weight, which had flown about half a mile over a lake. Langley further carried out very elaborate experiments on what were now called "lift and drift" measurements, that was to say, if the planes were properly set, a certain amount of lift was obtained by pressure upon the air. Upon that factor of propelling force at given velocities, and the amount of lift obtainable, rested the whole possibility of flight. He (the Chairman) came to the conclusion at that period that, with a full-sized steam engine, an aeroplane was perfectly possible. That was long

before Maxim attempted to realise the result on a full-sized scale. At that time his summary of the position was that with steam-power flying could be realised, but that it would be impossible to carry the necessary amount of water as an air-condenser, because of its weight, and that flight could therefore be maintained for only about half an hour. The light petrol engine had not then been evolved. At that time he was induced to go in for steam turbines, which was a very arduous pursuit and necessitated his abandoning the study of flying-machine questions. Ten years ago came the Wright brothers and other experimenters, many of whom lost their lives in developing the glider. That was the great obstacle in the way of the development of flying machines—the danger of the experimenters losing their lives. The author of the paper about to be read, Colonel O'Gorman, would deal with the present state of aeronautics. Beyond being a member of a few air committees, he personally had had practically nothing to do with aeronautics for the last thirty years.

The paper read was—

COMMERCIAL AERONAUTICS.

By Lieut.-Col. Mervyn O'Gorman, C.B., D.Sc.

Aerial Transport and Travel.

There is talk to-day of aircraft for transport and travel. The carriage of goods, mails, and people, the exploration of remote districts, the conduct of photographic surveys, the searching out of valuable trees in pathless forests, the speedy conveyance of officials to their administrations in distant climes—these things and others are everywhere hopefully dwelt on by the imaginative among those engaged in air work. It would be grossly unjust to say that such hopes and fancies detract from the energies which these persons expend on their war duties; they rather indicate the intention of winning and of carrying on thereafter the life of a virile community.

The public at large, like Gallio, cares for none of these things, and is a trifle jealous of any thinking which is directed to reconstruction. This attitude, though explained, is not fully warranted by war preoccupations. Once a month, when a bomb or so is aerially transported from Germany to London, we say: "Let us have a new Air Board, Air Council, or Air Ministry," but this can scarcely be described as original or effective thinking. A democracy has got to think, since it has chosen to govern; and when it realises that the mechanism which so easily brings those bombs, in spite of opposition, might very usefully carry a more amiable freight, it will be joining those who see a place for aircraft in our reconstruction. In a paper before the Aëronautical Society, in June this year, I gave reasons to show that in the interest of the war we must care about the future of transport by aircraft. I will recapitulate the position under *A*, *B*, and *C*, for there are three stages in the logic of the matter:—

A. We are to have an Air Ministry and an Air Force; the Act shows that they are not temporary—a token from which alone we may say that we intend to have a fighting Air Fleet.

B. An air fleet differs from a sea fleet in being much more easily expendible. No one would dream of rebuilding the British High Seas Fleet six or eight times per year of war, but an air fleet in action requires, and will continue to require, at least this. Thus the aeroplane has in this context the interesting singularity of being intermediate between a cartridge and a battleship. It is not quite so rapidly expendible as the former, but it is an expendible munition, and when we decide to have an air fleet we also decide, in logic, on the third conclusion, *C*.

C. This corollary is that we will maintain an aircraft construction organisation in peace that shall be competent to produce some six or eight air fleets per annum in war.

At present we have such an industry—not large enough perhaps, but we have at least a live and flourishing plant which is bearing fruit, which can grow, and which, be it noted, can also expire. A living organism can be killed by deprivation of oxygen. In three minutes a man is drowned, and forty years' training of brain and hand can be thus quickly reduced to an inert mass. Similarly rapid is the rate of disintegration of a highly organised technical production department like the aircraft industry, if it be starved. To-day war orders continue at full flood to fill up the wastage. If they stop suddenly we shall find within three months that the shop organisations are broken up, that all that remains to us is the husk; we shall realise that we could, by timely measures, have saved much of our expensively purchased experience and organisation, and have retained a value far greater than the mere buildings and plant. Once the designers and workmen are scattered, that which is so difficult and expensive to build up will be gone. Our capacity for the production of aircraft will be an object of derision like a bouquet of hairs in an old broom.

This simile will have succeeded if it has led a few score of persons to inquire, "What on earth are we to do to keep this mechanism of production in being without keeping up in peace the

war rate of expenditure?" A part of the answer was outlined in my first sentence; we must so utilise aircraft on commercial duty, and so nurse it in its days of trouble, that it shall itself earn the best part of its keep.

If aircraft using can be induced to pay, aircraft-making will of itself continue. But, in spite of the firmest belief in the value of aerial travel, the mere institution of services takes time. Neither three months, nor six months, nor a year, will see a thriving mercantile air fleet engaged on its routine duties, and issuing its routine orders on which the construction business depends. Yet a less period of inaction than this will extinguish the industry. This is the period I ventured to call the "hiatus" in the discussion on Mr. Holt Thomas's historic lecture last May. To bridge the hiatus we must do something *now*. There is no other alternative. No one expects a continued unrequited expenditure of from twenty-five to fifty million pounds per annum on aerial war material in peace time. On the other hand, no one would object to our making even this large amount of aircraft if it nearly earned its keep by remunerative services in any of the travel and transport businesses, or even if we could be assured that, after a period of Government support, it would eventually draw near to the standing of a self-supporting industry.

If we look back to the birth of the railway and the steamboat we see that for some years they struggled against public apathy—though their potentiality for good and for the creation of wealth and trade was almost as great in Watt's time as now. This apathy, amounting to boycott, rendered them unremunerative for a long period, and deprived the world of travel, and joy and change, and fresh air, and trade progress for well-nigh a generation. In the case of the road vehicle which we now call a motor-car, we had something worse than apathy—we had legislation for the alleged protection of the public, all meant in kindness—which killed the motor-car of 1837 and retarded the car of 1892, till France was well ahead of us. In the case of dynamo electricity we underwent a process of protective legislation against shock and fire possibilities, which threw us well behind Germany and the United States. The story of legal impediments to scientific advance makes one wonder whether we are a free people—that is, with freedom to advance, or are we only set on freedom to stagnate?

The greatest danger that aircraft has to fear, after public apathy, is legislative interference. It is not that the British law, excepting only when it is panicky, is worse made or more malignantly administered than another. The kindly intentions of legislation towards the public are generally as laudable as our laws in technical matters are detrimental. Yet such a community as ours can only live and thrive on its technicians. We are prone to drown the puppy lest he should bite, instead of adopting our own unique maxim of allowing the law to lag so that the puppy shall have one fair bite before he is muzzled.

We now know that it was shameful to have waited for the war before building up our Department of Scientific and Industrial Research. No branch of administrative expenditure was known to pre-war politics whose function was to venture forth, or to encourage us by press publicity, or otherwise, to advise the public to risk a little inconvenience during the period of evolution of a difficult art or science. The four-mile, the twelve-mile, and even the twenty-mile per hour motor-car speed limit prove that technical legislation has hampered and did not encourage. Of legislation relating to aerial transport it may safely be said that it is a case requiring the greatest delicacy of handling. It must be taken as certain that Government assistance, I do *not* say subsidies, for the industry must be forthcoming unless it is doomed; but even if this assistance were certain there remains cause for anxious thought to-day.

The danger of Government support lies in the conditions which a self-protective public is liable to impose before the technical possibilities are sufficiently known to form the basis for any sort of legislative interference. These conditions are liable to be all the more onerous since they could be imposed as of right, and regarded as a *quid pro quo* for the "*assistance*." The fearful might say that a great unknown risk to those on the ground (*omne ignotum pro magnifico*) is involved in any programme of commercial aeronautics. The braggart has already talked of a sky darkened by aeroplanes, of the cerulean clotted with colliding aircraft, and the timid voter silently wonders how *he* is to be protected from the *débris*. Luckily we have the facts with which to dispel this apprehension. To-day we may safely say that millions of pounds' worth of aircraft is yearly poured out from this country's factories. The large majority of this is flown to its destination, or used for tuition and defence at home, yet we still see the sun.

We have a full measure of the nuisance exag-

gerated by the more hurried training of flyers, and the extreme lightening of structure imposed by war conditions. Such nuisance as there is is purely local, and is really negligible. Now there is no prospect for many a long day of any such large output on commercial aerial transport. It is merely necessary to recall that our total expenditure on merchant shipping is a mere fraction of this to see the absurdity of apprehending and legislating as if we were to have this immense user of aircraft. There is no slightest probability of any nuisance in excess of what little we suffer to-day, even if we had, which I see we shall not have, an aerial fleet of this magnitude.

I have indicated the need for restraint in law making, but there is also need for positive official action, if the bells that ring in peace are not to sound the knell of aerial activity. The Allies must, during the war, frame a joint policy as to the tolerance of each other's trader and postal aircraft, and agree to air routes throughout the parts of the world which they control. With the large expanse of our colonies and our own industrial and postal importance, we have much to offer to the Allies which will be a valued equivalent for that which we shall obtain from them in the way of alighting rights. Living in an island, and accepting, as we must accept, the proposition that the most significant section of aerial transport will be outside the confines of Britain, we need that our Allied neighbours shall extend, not only tolerance, but welcome to our machines when engaged on their transport work. We and our colonies should have to be prepared and, I believe, are prepared, to extend a corresponding welcome to their airmen at home.

International agreements, even though simple in subject-matter and non-controversial, are always long drawn out. Everyone who understands factory organisation will agree that we cannot afford to wait until after the war for these parleyings to begin. Our aeronautical organism will assuredly become disintegrated too quickly. If we can get four or five willing men round a table to agree to admit aircraft mutually, to register them, to agree to simple preliminary rules of the road, and to agree that their respective countries should initiate a few lines of landing-grounds so as to constitute safe routes, the early days of trade flying have little more to ask for from the Foreign Offices of the world.

No doubt in some four or five years of active aerial transport organisation work the paltry fifty or hundred aeroplanes of our early post-war efforts at transport and travel will have grown up into a significant carrying trade for high-speed work, large quantities of aircraft will have been used for commercial purposes, and it will be found useful to introduce, and there will be experience enabling us effectively to introduce, valuable regulations for the protection of passengers in aircraft, and the public on the ground beneath. At the present day it is clear to all who have eyes to see that no adequate knowledge exists on which to frame rules with discrimination and without grievously hampering technical development.

I can imagine a legislator winning a round of applause from the *inane vulgus* by driving a hard bargain with the wretched trader, who, in the face of starvation, might accept any regulations, however hampering, in exchange for the means to live. I can imagine the imposition of tests of airworthiness, strength tests, the enforcement of hobbies such as multiple engines, silencers, special alighting gears, the carrying of parachutes, fire extinguishers, wireless equipment for calling for aid, and countless other things, which may, no doubt, come in their own time, but which would clog the versatility of the engineer, and for years condemn to unproductiveness the nascent industry of air travel. The payment of an army of inspectors would be put down as encouragement money, and would be a charge against the aeronautical vote. A landowner would ask for the power to capture the flyer who has most reluctantly alighted on his ground. He might ask for a law allowing him to impound the aeroplane, on the chance of his registered number being inauthentic, and so secure payment of the damages which he wishes to claim.

It is just possible that regulations of this sort might meet with support as much as support is at present accorded to the twenty-mile speed limit of the motor-car. They would be next to impossible to remove, though they might be demonstrably hampering the aircraft development of the country to an enormous extent. The intentions would be good, the desire would be to secure that only the best aircraft were used, and that the public suffered no injury by its use. It was for half a century thought that the public could suffer no injury by the four-mile speed limit being imposed on mechanical traction! Later it was thought that as a twelve-mile an hour speed limit was ample for a coach and four, it must be an ample speed for a car, and so the automobile industry passed to France and Germany, in spite of the fact

that the first car plied for hire in England early in the reign of Queen Victoria, when there was *no* speed limit.

Let us rest assured that the amount of civil aircraft will for some years be so much less than the amount of military aircraft now existing, that the total of damage to property and inconvenience to the public, which we at present know to be small, will be much further reduced in proportion to the lesser numbers, the future technical advances, and the less strenuous conditions of manœuvring imposed on peace aeroplanes

Labour.—Among the expectations based on aerial transport and travel are those of employment for individuals throughout the whole social scale, as well as officers and men from the Army and Navy. Our producers, and therefore their employment of labour, depend on the bodies which employ aircraft, viz.: (*a*) Primarily the Air Force; (*b*) foreign buyers, nations and colonies; and (*c*) companies instituted for transport and travel, including postal duties. All these bodies need labour, and all are interested in continuing harmonious relations between those who direct the work and those who manually carry it out.

It has been suggested that since the aircraft industry is a new industry, an exceptional opportunity exists of introducing a totally new atmosphere of harmony unembittered by the old trade quarrels. This is most desirable, but the novelty of the technics of aircraft has not *in fact* eliminated the old trades at all; on the contrary, it has developed the demand for these "tradesmen." The aircraft industry is not a new trade in the sense in which that word is used by the world of labour in the phrase "Trades Union." The aircraft industry includes members of almost all the engineering trades, as well as important additional trades, such as wood workers, carpenters, organ builders, cabinet makers, fabric workers, etc., and it is necessary for that harmonious relationship to be established between employer and employee, in spite of the fact that the history of all the old trade differences will unavoidably be also the history of the persons and corporate bodies imported into the new industry, with this addition, that a trade quarrel on the subject of organ pipes or on the piece-work price of chairs, may mean a stoppage of aeroplane work, owing to the newly imported craftsmen holding on to the old unions.

Again, it would be unintelligent to pretend that aircraft making can be developed under a compact between employees and managers which shall guarantee continuity of employment for all the manual workers in exchange for a continuity of labour supply to the other. The difficulty is a fundamental one, and perhaps is a worse difficulty in the aircraft industry than in most others. It is this. The technical developments of the art, the unforeseeable shortages of material, and the unavoidable changes of method and of materials, tend, let us say, at one time to the employment in an aircraft factory of 50 per cent. of wood workers and 30 per cent. of steel workers, and there is no human authority who can with sanity pretend to say that in some brief time these proportions will, or will not, be widely changed. If steel or aluminium were to form a greater part of the structure than they do now, because of safety, or diminished fire risk, or what not, any agreement with the wood workers' union for continuity of their employment would install them as a paid but non-working body of pensioners on the industry. Alternatively, British aircraft, hampered by such an agreement, would remain locked in its old technical groove and be debarred from adopting the devices and inventions which throughout the rest of the world would be improving the machine. Surely a hopeless prospect for a technical service required for war!

It is clear, then, that the agreements between manual and brain workers on aircraft must be part of the general agreement on which our new millennium is to be based.

Employment of Soldiers and Sailors.—The industry will, even when the most strenuous efforts have been made to save it by such continuance of air service orders as are at all possible, and when such aerial transport work is started as may be decided on, still be cut down drastically. Hence very great disappointment will be spared to many a good man by realising thus early that there will be no expansion of employment on aircraft which will absorb them wholesale, but rather a manifold shrinkage.

Accidents.—It is unfortunate that the chief contact which the public of England makes with aeronautics is in relation to accidents and casualties. The achievements appear, it is true, but it is almost impossible to visualise them save perhaps in the case of an occasional flight of unusual distance, such as the recent 3,000-mile flight from London to Constantinople, or between London and Turin, and these things appear to be disconnected items giving no

impression of the hundreds and thousands of miles of continual flying which is taking place. These show flights are few, not because they cannot be frequently achieved, but because war does not provide for show and *réclame*. The public cannot by a mere lecture be brought to the point of view which is standard with those who have been really familiar with aircraft; we are so imbued with its utility and versatility, that we are no more discountenanced by occasional breakages than we are deflected from hiring a taxi by seeing a sideslip against the kerb. Those actually engaged in design, who naturally need to use every element of experience which accidents may bring to enable them to perfect their work, are anxious to study and analyse these occurrences.

Air accidents can be divided into groups for the purpose of their study, and when we proceed so to divide them we find that by far the largest category includes those which are due to the two following circumstances: (1) The absence of landing-grounds distributed in easy stages to which a flyer can turn for refuge, if his engine should stop; (2) the inexperience of flyers themselves, since the majority of the experienced have been drawn off to the war. If we remove from the records of accidents, other than tuitional, all those which could have been avoided were these causes non-existent, the residue would be less significant in *fact*, and vastly less significant than is the *impression* abroad. Beyond this it is still reasonable and advantageous to subdivide the causes of this residue of accidents into classes, so that attention should be drawn to that which may be eliminated, be it in design or in handling.

Of the remainder, the most important is what is commonly called "Pilot's error." This does not imply that he is blameworthy. In war, manœuvres which are definitely hazardous are necessary; people may be surprised to hear that to loop the loop is a useful war manœuvre which may greatly puzzle an antagonist in the air, since the looped path takes the place of the expected forward movement, and therefore falsifies the aim of the adversary, or throws out all his estimate of the direction in which to fly for purpose of intercepting him. Another manœuvre, known as "spiralling," or "spinning," if contrived to give the impression that the aeroplane has in fact been thrown out of control, is one of many ruses for breaking off a fight. The learning of these manœuvres must be achieved before they can be used in war, and tends to swell the number of broken machines. Rapid diving, such as might be made in an attack on observation balloons, may similarly be a cause of accident until judgment is acquired in the method of "flattening" out of the dive. Even to describe a *very* small circle in a horizontal plane implies unusual stress on an aeroplane, if accomplished at high speed. None of these manœuvres are called for in trader work, while, to add to the comparative safety of the peace aircraft, we can appreciate the effect of removing the war demand for high performance and speed. Under fire and pursuit safety comes from lightness and manœuvrability, as much as and more than it does from strength and solidity: in trader work the conditions are largely changed if not reversed.

Aircraft travel and transport therefore will, if landing-grounds are provided, not be exposed to any of the risks above named, and accordingly from the list of accidents which occur to-day we must eliminate almost all these in any prognostication as to the future safety of flying. Before such an audience I need not belabour the so-called *air pocket*. It never did exist, and generally there seems to be little probability of any aeroplane, even when designed on the factor of strength used to-day, with the limited science of to-day, being broken in the air under the conditions of aerial travel.

Much need not be made of the fire dangers on aircraft, for when the matter is regarded dispassionately, the fire risk by actual experience is small. Of the fires which have occurred since thousands of aeroplanes have been turned out per month, the large majority have arisen when the aeroplane has struck the ground and the petrol vapour from the broken-up tanks has come into contact with a spark. Now this breaking-up of a machine on the occasion of a forced landing again becomes a rare occurrence if the line of landing-grounds suggested for aerial routes is provided. Most of these smashes, some fraction of which have resulted in fires, have occurred by reason of the flyer holding up his machine unduly long in his search for a suitable place to alight in a country where no provision for alighting exists.

Of the mechanical precautions taken to avoid fire, we know that already it has been possible to make a magneto which, when filled with explosive vapour and surrounded by it, gives rise to no ignition of the mixture. We have also learnt that the back-firing or "popping" of an engine into the induction pipe which throws a flame back can be made innocuous by drawing

the air supply of the engine from outside the body work. This, indeed, is standard practice to-day. The use of electrically heated clothes, called for by fighting at heights such as 20,000 ft. will not be normally desirable, and as for appliances for wireless telegraphy, which will have their place for giving trader craft their direction and for calling to the ground, they will not under peace conditions impose any risk of fire which cannot be circumvented. In general the standard of safety from this point of view will be automatically enhanced in all transport work. Carelessness, such as makes people bring matches into a T.N T. factory, cannot be expunged from the human race, but this class of occurrence need not disconcert us at all. In filling up with petrol there is the chance of spillages, and no doubt every aerodrome should be equipped with portable fire-extinguishers of light weight made available at filling points, and no doubt also all larger aeroplanes will carry one in an accessible position, until the proved absence of utility causes them to be relinquished.

The accident, if it can be so called, of losing one's way in a fog will be far less likely to result in disaster, when, to quote it once more, there exists a multiplicity of landing-grounds, because, on the one hand, no fog has been found to extend more than a very limited height, say, 700 yards maximum, and, on the other hand, because we now know that fogs are quite local in their occurrence at any one moment. A befogged flyer, instead of alighting through a foggy patch, merely moves a little further on before landing. This does not imply that projects for signifying to a flyer who is above the fog the correct position of his aerodrome by pilot balloon or raised lights are to be discarded, but this is not the place to deal with that point.

Parachutes are spoken of, but by many flyers are not thought particularly desirable. We know that at present they require a height of some five hundred feet to open out and afford the safety which they appear to offer, and it is usually below these levels that the flyer becomes convinced he is to be exposed to some risks, say, by the conditions of the ground together with the stopping of his engine which causes him to alight. One would have to be very seriously out of touch with those who fly daily and really know their job, if one continued in the impression that numbers of accidents are the inevitable concomitant of aerial travel, and it is sufficient to say that any such opinion may be dismissed as one which has arisen from the peculiar conditions of press publicity in war and the exclusively high pressure and high performance conditions of the development of aeronautics up to to-day. The lack of contact of the public with the serious and successful work which has been achieved has already been mentioned.

Research.—It is possible that someone will question the need for research and for State endowment thereof; it may be said that we are well on and can now trust to practical developments, since root and branch retrenchment of expense is called for. This is a complete *non sequitur.* If cheap progress is wanted, the cost of progress is enormously reduced by making and testing models two feet wide instead of making structures of a hundred-foot span. The ratio of cost is as £10,000 to £50, and it is the £50 scheme which I am advocating. I cannot give a list of researches, but ask you to consider the following examples. We need the scale corrections from model parts to full size; we need to test propulsive mechanisms, without building them; we must know the value of new wing sections; of reflexed wings; of hinging the flaps for controls; we must, in order to get any aeroplane stable, know the movement of the centre of pressure on the wings when the attitude of flight is varied; we must study the effect of vibration on structural parts, etc.

We are aware that the great utility of aerial travel is speed, that the great enemy of speed is head resistance, and we must be able by simple model tests to forecast the speed which will be attained by a given design. We must be able to know, before we introduce a variation in design, the amount of economy of resistance which can be made by altering structural parts. All this class of work can be effected in the wind tunnel, and already most serious aeronautical construction firms are equipping themselves with a wind tunnel. Probably the greatest value of such equipment is its educational effect. The wind tunnel has fought its way to the front, in spite of much opposition, and it is still to be recognised that unless its indications are interpreted by skilled persons grave blunders will be made, but this in no wise detracts from its utility when properly employed.

We are aware that the thermal efficiency of engines employed on aircraft is as high, in spite of their small size and weight, as the efficiency of Diesel engines giving thousands of horse-power. Yet this figure is only 30 per cent., and by research alone can we hope to obtain an extension of this percentage. The study

of airscrew efficiency, the effect upon it of the body, the means for making airscrews smaller than they are at present, and thereby simplifying the whole outline of an aeroplane, is a matter which research must tackle. The use of new alloys, of new methods of totally enclosing the flyer in an aeroplane, new methods of housing the landing gear, so as to get rid of its head resistance, the protection of the fabric of the wings from disintegration by ozonisation due to actinic light, all these and countless more matters can only be economically and expeditiously studied in laboratories equipped for the purpose, they will effect enormous economies in aeronautical upkeep, and aero research must be pressed on and financed after the war.

Broadly, it may be said that air transport will not develop save by taking a line of footprints given by research. To say that we want it, does not by any means ensure that it will proceed apace as it should. Research of various kinds is remunerative in two different ways: (*a*) quickly; and (*b*) eventually. Those studies which conduce to (*b*) rarely produce (*a*) a quick return. On the other hand, researches which afford us (*a*) are very likely indeed to be remunerative both quickly and eventually.

If we now subdivide the various researches which might forward aeronautics into two other classes—those (*a*) which result in some proprietary advantage to the inventor, and those (*b*) which have a general effect on progress, and which are not susceptible of being privately protected—we find that there is every inducement to the research worker to concentrate upon the class of improvement which I have called (*a*) in each of the above pairs of groups, that is to say, the device which can both be made proprietary and which is remunerative quickly.

This must, unless we are very foreseeing and courageous, operate to deflect research workers from the other and frequently much more important class of study, viz., those which are of *general* application and those which are eventually of great money value to the whole of the industry, whether of construction or of transport.

Patent laws stimulate advancement by providing that there shall be a reward, and that all and sundry shall not be able to possess themselves of the fruits of one man's labour and thereby dispossess him. Means must be devised for securing that the British industry as a whole shall not be tempted to exclude from its study the great groups which I have classed as (*b*), which are so frequently not protectible by patent; and this business falls naturally to the new Department of Scientific and Industrial Research, who will no doubt find the hearty co-operation of the Society of British Aircraft Constructors and the Aeronautical Society. It is for the public to see that the determination towards progress exists, and then the outcome will first of all be the necessary funds, and thereafter the harvest of results and economies.

The Air Board has formed a Civil Aerial Transport Committee, which is engaged in considering these and most of the other matters dealt with in any such discussion as this, and if they recommend active steps to be taken, let us hope that there will be firm public support for any expenditure and assistance which shows proper foresight, always with the considered approval of the new Air Minister.

Education.—It is more than probable that by far the most effective step towards industrial peace, with which is bound up much more than ever the healthy development of our aerial fleet, is education; and this aspect of the matter forces us to include what is sometimes overlooked in technical circles when speaking of education—a good foundation of sociological and ethical subjects, as well as technical information. Perhaps one of the most important reasons for developing this side of education is that it will give the average reader a more critical outlook upon the average newspaper, and its somewhat unguarded statements. The effect of this critical outlook will no doubt be that a far higher technical standard and a more cautious statement of alleged facts will be developed, and in this way the educational effect of the press will react to further the educational standards. It will not, we hope, be possible, a few years after the passage of Mr. Fisher's Act, for any person who pretends to a hearing to claim that there is a pool of wealth of limited total from which each and several draw as much as they can. That illusion is the foundation of the impression that the employees suffer by the employer being successful, and we shall all gradually come to accept that by restricting the production of wealth we diminish the chance we individually have of being wealthy.

The indirect abolition by Mr. Fisher's Act of the blind-alley occupations, will have also the effect (since we have decided to be governed by a body which includes many of those who live blindly in blind alleys at present) that a more farseeing electorate will have charge of our destinies. So far as the hand-workers

in aircraft construction are concerned, they do not differ from the engineering trades generally, and the educational scheme which is good for the skilled fitter or carpenter is good for the aircraftsman. In the higher branches, *e.g.* the aeronautical designer, what is first wanted is a good engineering and sociological education, to which are to be superadded the specialities of his calling, a business largely to be achieved by familiarity in college or university with the work of the wind tunnel and whirling arm.

Routes.—One of the things wanted now is some inquiry made experimentally by actual flight for the purpose of determining the best aircraft trader and postal routes which may be useful and eventually payable. London–Paris has been suggested, with extension to Marseilles, Turin, and Egypt. Links between capitals have also been spoken of, and links with India and South Africa, etc. Short runs will probably come first. In all short distance runs the problem is complicated when the existing rail and steam facilities compete. There is a marked advantage for aircraft every time that transhipment of any kind occurs on the ordinary means of transit. This favours London–Paris and London–Dublin, for example. Similarly, and for similar reasons, whereas no great advantage might be gained by a London–Glasgow route, where the train travels at fifty miles per hour, and the journey can easily be done during the lost hours of the night without the traveller being roused from his sleeping berth, we shall find that cross-country journeys, those involving changes of train, waiting at stations for connections, will be instantly eclipsed in comfort and speed by aerial travel and aerial mail deliveries. One could suggest Cardiff and Newcastle, or the like.

I do not think that much is to be gained by suggesting routes at the present moment, unless we propose to permit a few machines to be withdrawn from war service, and then by using a few pilots who are for one reason or another not fit for war service, explore the practical possibilities of such transport. I think it far better to start by carrying newspapers and letters, and packets, rather than passengers at first, for every reason. The routes will be unknown to the pilots, their experience may perhaps not be great—the advertisement expense needed to summon passengers to support the trial cannot usefully be made in war time, and, generally, it is not desirable, save in exceptional case, to expend petrol for personal travel, or to expend money in adapting designs to passengers' comfort. Yet if this comfort were omitted, a false impression of the facilities to be afforded would easily get spread abroad.

I do not know whether certain types, whose performance is below the ever-rising requisites for war could be made available, but I should have thought that with good will they could be managed, and if so, the experiments made in war time would help us to start *quickly*, on declaration of peace, that which might eventually help to create orders—only a few it is true, but still a small fraction of what is wanted for the maintenance of the production factories.

Speed.—I am inclined to endorse Mr. Holt Thomas's view that, if we consider the average wind speed as thirty miles per hour, sometimes with us and sometimes against, we shall need machines whose own air speed is 120 miles per hour, in the case when there is any competition with other means of transport.

On cross-country journeys far lower speeds will be vastly faster than the existing systems, and will at once command attention.

As we know, 120 miles per hour is a very ordinary speed to-day for aircraft, and offers no technical difficulties in alighting—indeed, Captain Green's interesting forecast, under certain conditions which he laid down, of an aeroplane to travel at 240 miles per hour, did not appear to raise any feeling of doubt or hesitancy at the Aëronautical Society about three weeks ago—though a similar audience in 1911 was very sceptical about the advisability of introducing, even for military purposes, my proposed speed of seventy-two miles per hour. This gives us an idea of the changes which have gone on in men's minds by legitimate extrapolations from the actual achievements with which they are familiar.

I have nearly finished, but before doing so I must once more reiterate that the most hopeful estimate for immediate aircraft transport and travel does not save the situation. There must be Governmental action to maintain the country's productivity and designing capacity for military and naval aircraft in the first place, and as the mainstay of the country's factory organisation.

In conclusion, it is only half a truth to say, with Frederick List, "The sea is the high street of the earth. The sea is the parade ground of the nations. The sea is the arena for the display of strength and enterprise of all the nations." There is now the air. A great instrument of power tending to peace and usefulness and good will can be designed in a week, if only a British, a French, an American, an Italian plenipotentiary

could be empowered to sit round a table. That instrument is the aerial way. Its regulations must not be founded now upon speculation, they must be evolved later upon experience.

All the Allied nations desire the same thing, all are agreed that just as in time of peace we must prepare for the catastrophe of war—so in war we must prepare our thoughts and plans for the cataclysm of peace. The word is used advisedly, for a very sinister situation will develop in the world of aircraft during the hiatus which first was publicly indicated, I think, by myself, in the discussion on Mr. Holt Thomas's paper before the Aeronautical Society, and which Lord Cowdray himself promised to make every effort to bridge.

DISCUSSION.

Major S. Heckstall Smith agreed with the suggestion made at the end of the paper with regard to immediately employing aeroplanes for civil purposes. They were already being used in France to carry mails, and the same practice should be adopted in this country as soon as possible. Those employed in aeroplane construction were afraid that after the war they would be left without employment. If they were assured that they would be able to continue their aircraft work after the war they would be glad to do so, but they were so afraid of the hiatus between any commercial work and the end of their war work, that they would all turn their thoughts and plant to other engineering work. That would be a very unfortunate thing for the country, and it was therefore of the utmost importance that aeroplane builders should be told at once what their prospects would be after the war, and the powers that be should be urged to decide the matter promptly.

Mr. Harry Harper thought it would be a very good plan to call an international conference between the Allies, before the end of the war, to frame some simple rules of the air, and also to discuss the laying down of certain aerial routes. It would be very difficult to make any progress until that was done.

Captain Swinton endorsed very heartily all that the author had said in his paper. It might be of interest if Colonel O'Gorman could give some information about the rate of depreciation which was to be expected on commercial aeroplanes. That depreciation would probably be a much more important factor than the cost of fuel. He had heard all kinds of estimates given, from $33\frac{1}{3}$ to 180 per cent. per annum.

Mr. J. F. Crowley said he had been very much interested in Colonel O'Gorman's paper. With regard to aerial routes, he thought an air service might be established between Galway and America for the purpose of carrying mails, thus considerably shortening the time taken to carry letters between this country and America. It would be very interesting if the author would say what he thought of the Zeppelin as a possible rival to the aeroplane. Before the war, a friend of his had been appointed by the German War Office as designer of the rotary apparatus for the Zeppelin airship, and that gave him an opportunity of visiting some of the Zeppelin sheds and seeing the vessels in action. He was very much struck, as an engineer, with the extraordinary perfection of their design, and since then they had, of course, been greatly improved. The shape of the body had been altered so as to reduce the friction, the speed had been increased, and altogether the Zeppelin had made very great advances. In working out any scheme for the commercial development of the aeroplane, it was very desirable to know from experienced men like the author what position lighter-than-air machines were likely to occupy for commercial purposes.

Mr. Walter F. Reid did not quite agree with the author that the nuisance possible in connection with aeroplanes was negligible. Personally, he thought that nuisances should be very seriously considered, as there was nothing more injurious to the progress of commercial aerial navigation than opposition on the part of individuals who might possibly suffer from some slight nuisance. The development of the motor-car had been greatly impeded in that way. A large number of aeroplanes passing continually over a certain place might easily give rise to complaints from people residing in that district, and there should be a central fund out of which to compensate them for any injury, such as the fall of aeroplanes. With regard to Captain Swinton's remarks about the cost of the renewal of aeroplanes, it should be remembered that they did not require an expensive line of rails, such as was needed by railways, and he thought aerial transport ought to be extremely remunerative, both to the public and eventually to those who constructed and ran the machines. The latter might very well afford to pay a small subscription towards the compensation fund that he had mentioned. The author had referred to the injury that might be caused to aerial transport by technical legislation, and it was quite true that such legislation might hamper the whole progress of Great Britain in regard to a new industry in which she ought to lead, as she did in the case of the locomotive industry. Already a Bill had been introduced into Parliament to propagate the system of mismanagement that had been going on in the different Government departments with regard to the purchase of materials, and another Bill that was now before Parliament contained a clause by which the Comptroller of the Patent Office was to be the judge of whether an invention was worked on a commercial scale in this country.

He was to have the power to preclude the patentee from himself working or using his invention. Any capitalist could say that a certain invention had not been worked on a commercial scale in this country, and he could get the Comptroller to hand over the invention to him on payment of a royalty, the inventor being thus precluded from working his own invention. That was not the way to encourage invention, and under laws of that kind this country could not possibly compete with the United States or Germany, or any other country where the inventor was properly treated. Research in connection with the aeronautical industry was of the very greatest importance. He had been chairman of several of the experimental committees of the Aeronautical Society, which found out many things that had not been touched since, but which offered a vista of enormous improvements in the flying machine. For instance, the propeller of the aeroplane was not, in his opinion, the best that could be evolved; it was wasteful in power, and had other great disadvantages. It should have a certain amount of elasticity which would enable it to be adjusted to the power that was being put into it, but at the present time the propeller was rigid, and was not adjustable at all. With regard to the utility of research, he would like to call attention to the very useful work that had been done by the Advisory Committee on Aeronautics, work that had helped the industry very much indeed. He was the originator of that committee when he was a director of the National Physical Laboratory, and it had done very good work, although it did not at the beginning do what was expected of it in regard to full-sized aeroplanes. He hoped that similar research to that carried out by the committee would be undertaken on a large scale. With regard to the standardisation of aeroplanes, he was an opponent of standardisation if it meant that for four or five years the same kind of machines had to be ordered, made in exactly the same way, with interchangeable parts. That meant simply stagnation. The committee entrusted with the work of standardisation should meet once a year, or even more frequently, and consider where the standard already adopted was defective, and where it could be improved, and then, with the agreement of all the makers and users of aeroplanes, those alterations should be made at once. If the different kinds of machines were limited in number, and all the makers interchanged their ideas, as they might do, then spare parts could be obtained at all the different stations where aeroplanes might alight, which would be a great advantage. He had devoted a great deal of attention to the subject of landing-places for machines. In England, if the authorities would only use them, there were better methods of illuminating aerodromes at night than were available in France, although France was formerly ahead of this country in that respect. The stations at which aeroplanes were to alight should be from the very first planned at regular intervals throughout the whole country, in connection with the population and the adjacent towns, etc., and a committee should be appointed to decide where the stations were to be erected, in order to avoid the more or less haphazard method of building stations that had been adopted by the railways when they were first constructed.

Mr. Leon Gaster said that the paper was of great interest to him, as he was a strong believer in the future industrial possibilities of the aeroplane. He recalled that, when present at a paper read before the Society by the Rev. J. M. Bacon in that very room about eighteen years ago, he had expressed the opinion that the solution of the air problem would be found in a heavier-than-air machine, rather than one depending on the buoyancy of a gas-envelope. Time had proved the correctness of this observation, though it was made five years before the flights of the Wright brothers and the subsequent development of the aeroplane. Whilst agreeing with the proposition of the author that everything possible should be done now to prepare for the future use of aeroplanes in the manner indicated, and appreciating the practical way in which he had dealt with the problem, Mr. Gaster thought that Colonel O'Gorman had rather given the impression that he cold-shouldered the idea of passenger traffic. That was, in his opinion, a development that was bound to come. Although the experimental difficulties might be considerable, advantage might be taken even now of the facilities offered by the Department of Scientific and Industrial Research for investigations in this field. He believed that the future possibilities of aircraft for peace purposes might prove more wonderful than their present applications for war. He looked forward to the time when science would once more be put to its proper use, and when the aeroplane would become a connecting link between peoples instead of an instrument for the indiscriminate slaughter of non-combatants in defiance of the laws of humanity.

Colonel O'Gorman, in reply to the discussion, said he did not mean to throw cold water on the eventual prospects of civil aerial transport, as Mr. Gaster had suggested. There was no question to his mind but that commercial aeronautical development was bound to grow, but if we simply felt convinced that we had a nice healthy infant that would grow up without any trouble on our part, then what would happen would be that that infant would die from neglect. It was necessary that it should be fostered with the utmost care, and that immediately. He was glad no speaker had complained—as he rather expected some might do—that the question of civil aeronautics should not be discussed during the war. After all, we were fighting the war for the purpose of carrying on the existence of this community, and if we failed to think about the business of this community during the war we should fail to exist afterwards. If the war was

ended to-day, then the aircraft industry would die; aeronautical construction would cease, and there would be nothing for the aircraft factories to do. He strongly urged that steps should be taken at once in preparation for the time of peace. With regard to the question of nuisance raised by Mr. Reid, it was true that if there was a nuisance, however small, arising from aircraft, there were sure to be complaints. Half-a-dozen people complaining of the noise in the morning, however, was a very small matter compared with the advantage of having the whole of England protected against a sudden aeronautical attack, should war ever break out again. He did not wish to suggest that the nuisance was negligible, because it certainly deserved consideration. It consisted mainly of noise, and sound was a science about which very little was known at the present time, and which was greatly in need of research. He was afraid that legislation might be introduced to treat the noise of aeroplanes as an adequate cause for imposing regulations which might very easily strangle the whole aeronautical business. With regard to rigid airships, he had always upheld airships ever since the first moment when he had an opportunity of building them. Not very long before the war he had the good fortune to make a trip in a rigid airship in Germany. It was interesting to know that per pound of useful load carried an airship was to-day a cheaper implement than an aeroplane; that did *not* imply that, if it was desired to carry goods from one place to another the cost per pound of goods carried was less in the case of the airship, but only that the prime cost of the airship alone was about one-eighth or one-ninth less than the cost incurred in the case of the aeroplane. There were, of course, other factors to be considered in comparing the two; for instance, when an airship alighted it required a large landing party. The question of the airship *versus* the aeroplane was a complicated problem, on which profound study must be made before one could even guess at the solution. Until aeroplanes could be adapted for long-range sea scouting, this country would require to use airships for that purpose. He thought the suggestion made by Mr. Crowley of an aeroplane mail service between London and Galway, to catch the American mail ships, was a very good one. With regard to the rate of depreciation of aeroplanes, it must be remembered that in time of war the depreciation was very much greater than it would be in time of peace. Aeroplanes used on war service were exposed to all kinds of dangers, and the life of such an aeroplane was probably only about one-and-a-half to two months. Aeroplanes employed in civil work would probably have a much longer life, but the question of their rate of depreciation strengthened his hands in the plea he put forward for the necessity of experimenting with commercial aeronautics at once. Perhaps the fact, mentioned by Major Heckstall Smith, that aeroplanes were already being used in France to carry mails might hasten the time when England would attempt something similar. As regards the suggestion for a central fund to repay the public for damage received by an aircraft alighting on their crops, etc., he saw no reason why the owner or flyer of the craft should not be held responsible to repay in full the damage, without any central fund. That was not the class of legislation he objected to. He had no desire that the aircraft transport industry should escape this legitimate burden. What he did object to, and actually apprehended, was there should be regulations framed which would be intended to protect, and would protect a few householders from, for example, the noise which they might suffer from by being near an aerodrome. The noise of a passing aeroplane was much less than that of a railway train entering a station, yet we found that it has been well worth while to bear the local drawbacks of this noise to individuals residing on the railway line for the sake of the enormous advantage to the community of having the railway service. Similarly, the aircraft noises, which were an annoyance just now, were objections outweighed by the advantages of speedy transport. Legislation, prescribing, let us say, some ridiculous height of travel above the houses near an aerodrome, might secure the absence of noise, not only because of the height of flight, but because of the killing of the aircraft business and the consequent absence of flying. This last was the consummation to be guarded against, and he still maintained that the noises due to aircraft about the country were to-day a negligible source of nuisance compared to the advantages. He thought Mr. Reid was unintentionally unfair in blaming the National Physical Laboratory for not doing full-scale research work on the aeroplane, for the reason that full-scale work had never been referred to them, and they had not, nor ever had, any means or staff for dealing with it.

THE CHAIRMAN (the Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.), in moving a vote of thanks to the author for his interesting paper, said he was very much interested in the question of technical legislation with regard to aeroplanes, because such legislation had prevented the progress of the motor industry for very many years, and at a later period had acted very detrimentally in the electrical industry. In this country we were so anxious to protect the individual that we often stifled progress. The Committee on Scientific and Industrial Research had now considerable funds placed at their disposal, and were trying to do all they could to assist unremunerative researches. Last year the committee spent £12,000 on experiments, and this year they would probably spend a very much larger sum.

The vote of thanks was carried unanimously, and the meeting then terminated.

THIRD ORDINARY MEETING.

Wednesday, December 5th, 1917; Alan A. Campbell Swinton, F.R.S., M.Inst.C.E., M.I.E.E., M.I.Mech.E., Vice-President, and Chairman of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Berwick, F. W., London.
Delpech, Reginald, London.
Hackett, W. W., Birmingham.
Hall, Robert Swainson, Portuguese Congo.
Lake, Joseph Lenegan, London.
Lambert, Arthur Reginald, Sevenoaks.
Laws, Robert George, London.
Samuel, Henry, London.
Seth, Mesrovb Jacob, Calcutta.
Waring, S. J., London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Aplin, William, Assoc.Inst.M.M., Queensland, Australia.
Armstrong, Ernest, Haydon Bridge, Northumberland.
Banatvala, Curtsetji Jamsetji, B.A., Bombay, India.
Bayley, Victor, C.I.E., Assoc.M.Inst.C.E., Simla, India.
Bhándare, Rao Bahadur S.T., Inspector-General of State Records, Gwalior, Central India.
Blair, Lieut. John Hamilton, R.N., D.S.O., Submarine Depôt, care of G.P.O., London.
Clowes, William Archibald, Ditton Hill, Surrey.
Collier, Harry Samuel, Buckland, near Betchworth, Surrey.
Cox, W. Howard, Cincinnati, Ohio, U.S.A.
D'Abreu, Aubyn Reginald, Mesopotamia Expeditionary Force.
Dhruva, Maganlal Dhaneshwar, Rewakantha, India.
Gwyther, Harry Earlston, M.Inst.C.E., Rio de Janeiro, Brazil.
Hamshaw, William Hamlin, J.P., London.
Hancock, Walter Charles, London.
Hay, Leslie, Messrs. Finlay & Co., Ltd., Calcutta, India.
Henriques, Elias Cosmas, A.R.I.B.A., Bombay, India.
Hutchinson, C. M., B.A., Pusa, India.
Jack, Robert Ernest, I.C.S., Calcutta, India.
Jennings, Frederick W., London.
Johnson, Arthur Laurence, M.A., Middlesbrough.
Johnson, Harold, Bombay, India.
Jones, F. J. Clinch, Northenden, Cheshire.
Jordan, Frank, Swansea.
Kemp, Walter Lowther, Singapore, Straits Settlements.
Krishnagar, Maharaja of (Kshaunish Chandra Roy Bahadur), Bengal, India.
Kroll, Clifton H., San Francisco, U.S.A.
Laird, James, London.
Lang, Rev. George, Alabama, U.S.A.
Locker, Thomas Cecil, A.M.I.Mech.E., Warrington.
Macdonald, James, Hong-Kong, China.
Makower, Ernest S., London.
Matthews, Dr. Joseph Merritt, East Orange, New Jersey, U.S.A.
Mawson, George Thomas, Bombay, India.
Mews, Walter, Portslade, Sussex.
Molson, John Cavendish, M.D., L.R.C.P., F.C.S. Hayward's Heath, Sussex.
Moore, William Withers, London.
Muto, Sanji, Hiogo, Japan.
Naidu, Mallem Chengalvarayulu, Rangoon, Burma.
Nashipur, Maharaja of (Ranajit Sinha), Bengal, India.
Nicholson, Harry, B.Sc., London.
O'Leary, Very Rev. Peter J., Sligo, Ireland.
Poulsson, Ths. H., Stavanger, Norway.
Richardson, Robert Taylor, J.P., Barnard Castle, Co. Durham.
Rowell, Herbert, M.Inst.C.E., M.I.N.A., Jesmond, Newcastle-on-Tyne.
Ruthen, Charles Tamlin, L.R.I.B.A. M.S.A., London.
Santosh, Raja of (Manmatha Nath Ray Chowdhury), Bengal, India.
Scott, James Lang, Bramley, Surrey.
Shewan, Hon. Robert Gordon, Hong-Kong, China.
Sneath, William H., Ryfylke, Norway.
Solman, Harry, London.
Starr, Louis, M.D., LL.D., London; and Philadelphia, U.S.A.
Tait, William Archer, D.Sc., M.Inst.C.E., London.
Tarlton, Edward Smedley, Barakar, India.
Tobutt, John James, London.
Waite, Captain C. S., C.I.E., Delhi, India.
Wee Guan Toh, Sandakan, British North Borneo.
White, James, Commission of Conservation Ottawa, Canada.
Wilcock, Arthur, London.
Wilson, Anthony, J.P., Braithwaite, near Keswick, Cumberland.
Wilson, Leonard, Washington, D.C., U.S.A.
Wood, Sir Henry Trueman, M.A., London.
Wright, A. J., L.D.S., D.M.D., Perth, Western Australia.

The Chairman, in opening the meeting, said that the lecturer, Sir Dugald Clerk, did not need any introduction from him, as he was well known throughout the scientific world. It was singularly appropriate that Sir Dugald Clerk should give the first of the "Trueman Wood" Lectures, because he

was the originator of the idea of commemorating Sir Henry's long period of service as Secretary of the Institution. Sir Henry Trueman Wood retired from the secretaryship at the close of Sir Dugald Clerk's term of office as Chairman of the Council, and it was the latter's happy inspiration to commemorate Sir Henry's services by the institution of the "Trueman Wood" Lectures.

The lecture delivered was—

TRUEMAN WOOD LECTURE.

DISCOVERY AND INVENTION.

By Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., M.Inst.C.E.

The Council of the Royal Society of Arts, on the retirement of Sir Henry Trueman Wood from the important office of Secretary, after forty-five years' connection with the Society, desired to mark their sense of the great services rendered by Sir Henry by instituting an annual lecture to be delivered at the Society. This lecture is to be called "The Trueman Wood Lecture," and, in accordance with Sir Henry's wishes, it is intended to discuss some interesting point or problem in connection with the application of science to the needs of civilisation.

Sir Henry Trueman Wood has had a lifelong experience of science in every possible application to the good of mankind. He was educated at Harrow and Clare College, Cambridge, and it is interesting to note that he studied for the Classical Tripos and became Le Bas University Prizeman in 1869. Sir Henry's classical education did not in any way, however, prevent the growth of an intense interest in science and industry, because we find him as early as 1870 engaged in H.M. Patent Office as a Civil Service clerk at the age of twenty-five. Two years later he became editor of the *Society of Arts Journal*, while Le Neve Foster was Secretary. He edited the *Journal* for four years, and in 1876 became Assistant Secretary, and in 1879 Secretary, so that while he has been connected with the Society for forty-five years, for thirty-eight years he has beneficently controlled our destinies. Undoubtedly for nearly forty years the success of the Royal Society of Arts has been due to the ability, industry, and great capacity as an organiser, of Sir Henry, as well as to his vivid interest in every mode of serving our country by the encouragement of scientific industry. In addition to the work of conducting the affairs of the Society, he gave important aid in connection with the Inventions, Colonial, and Health Exhibitions. He was British Commissioner to the Paris Exhibition of 1889, and he received the honour of Knighthood in 1890 for his services in promoting the success of the British Section.

Sir Henry is a skilled photographer, and was President of the Royal Photographic Society from 1894 to 1896. His knowledge of mechanical science is also shown by the fact that he acted as Honorary Secretary to the Mechanical Science Section of the British Association for six years, from 1878 to 1884. He is the author of two important books, "Industrial England in the Middle of the Eighteenth Century," published in 1910, and "The History of the Royal Society of Arts" in 1913.

Sir Henry has led a most active life, devoted to the welfare of his country by encouraging in every way the application of science to all the needs of mankind. It is most fitting, therefore, that "The Trueman Wood Lecture" should be instituted in his honour, and that it should deal with different phases of the development and use of scientific discovery and inventions.

I feel it a high distinction to be requested by the Council to give the first of the series of lectures in honour of our friend and co-worker, Sir Henry Trueman Wood. I have accordingly chosen as my subject the consideration of some interesting matters in connection with Discovery and Invention.

Our distinguished Chairman of Council, Mr. Campbell Swinton, has just given us an admirable address of wide scope dealing with the general history of Science, and accordingly I propose to confine myself to the discussion and comparison of Discovery and Invention in some detail in a manner intended to be supplementary to his interesting account.

DISCOVERY AND INVENTION.

In the present time, when reconstruction problems require a true appreciation of the proper function of Science in the State, it is important to form clear and accurate ideas as to the differing nature of Discovery and Invention, in order that Science may be given due weight in the coming scheme of things. Even scientific men think somewhat loosely on this subject, and often confuse the functions of discoverers and inventors. It is too often assumed by specialists of a certain type that discoverers are also inventors, or at least could be inventors whenever they chose to descend from the important realms of abstract scientific investigation to the—as they think—easier business of producing inventions for the practical needs of civilisation. As a matter of mere fact, discoverers are hardly ever inventors; the type

of brain power which is found in great discoverers is quite different from that of the great inventor.

Scientific research in physics and chemistry is of two kinds: one kind deals with the nature of the phenomena observed, and endeavours to arrive at some soul-satisfying explanation of the why and wherefore of the particular occurrence; the other endeavours to discover hitherto unknown phenomena. Naturally the earlier investigations dealt with known phenomena, and one type of discovery consisted in determining their laws. Newton's discovery of the laws of gravitation dealt quantitatively with the fall of matter from a height, and applied equally to the motion of worlds and the fall of a stone. The facts were known, and the discovery consisted in the determination of the law of the fall and the measurement of a pull at any distance—a few feet or thousands and millions of miles. The discovery, however, of a numerical law does not constitute an explanation of a phenomenon. Gravitation is as great a mystery now as in Newton's day; no explanation has been forthcoming, no possible mechanism has been conceived to enable us to understand the nature of the attraction of one particle of matter for another, either at atomic distances or at the huge gaps of interstellar space. Newton's discoveries supplied the law, but not the explanation. So far science has often been able to supply the law, but never the explanation. Many laws are known with considerable accuracy, but all reasoning on the facts leads up to the contradiction which inevitably follows the closer application of thought to theories of gravitation, cohesion, light, electricity, chemical action, and life; all appear equally inexplicable. The object of the more highly abstract scientific investigation is to find some reasonable explanation of the universe, and this can only be attempted by the close examination of all phenomena and the discovery of phenomena hitherto unknown, then the determination of such laws as can be dealt with by the senses with which Providence has gifted us, aided by the use of special instruments to extend their scope.

The research then consists in weighing matter, measuring volumes, velocities, light intensities, and so forth, which accompany the particular occurrence and attempting to deduce a law. From the law and nature of the action a theory or hypothesis is formulated, either by induction or deduction, which appears to account for some, if not all, of the facts. When the investigation reaches this stage it is usually felt that the phenomena have been explained. So far, however, science has failed as completely on the material side as philosophy has on the intellectual in furnishing us with one complete and altogether true conception of any action whatever. What is commonly called an explanation merely refers the mind to familiar actions in matters which permit of numerical determination. When the new or unfamiliar becomes analysed into familiar constituents the new phenomena are said to be explained. The work of abstract science so far has consisted in the determination of the sequences of phenomena which occur within our experience, and in disentangling in these differing sequences occurrences which are called electrical, gravitational, thermal, etc., referring in fact differing phenomena to a common class.

Although no real explanation of any occurrence has yet been found, this does not prevent us from predicting the effects of alteration in circumstances, because the law is often known, and whether we understand it or not, the law permits us to know what will happen.

Thus, although we have failed to understand gravitation, we can rely on the great law that attraction between bodies varies directly as the mass and inversely as the square of the distance. We can rely so far on the generalisation that within our experience matter is neither destroyed nor created. The great laws of thermodynamics, the mechanical equivalent of heat, and the law of heat conversion, known as the second law, may also be used for prediction. Numerous other laws are used for prediction, and the prediction in the form of an experiment or machine is found to be accurate notwithstanding our ignorance of any real explanation. Practical use can be made of the facts without fully understanding them.

The object of abstract investigation is to endeavour, by questioning nature, to accumulate a sufficient basis of fact and law of sequence ultimately to arrive at some comprehension of the nature of matter and energy in its different manifestations — physical, chemical, and biological. This is the fascinating work of the abstract investigator, and its pursuit is of the utmost importance to mankind, apart altogether from any question of material gain. It is, and should be, conducted without any aim other than true understanding; nothing but abstract truth is its object.

The complexity, however, of all nature is so great that progress can only be made by each investigator devoting his life to a comparatively

narrow field. The world of actions found in the atom and molecule by the modern investigator are almost infinite in their variety, and life is all too short for one man completely to elucidate even a relatively small class of fact. Such work is of world-wide importance in the development of the reasoning power of man, and the hope may be held that in the future our intelligence may rise to enable us to attain a real, if not complete, understanding of the marvellous world in which we find ourselves mysteriously gifted by the Almighty with consciousness of ourselves and our surroundings, and reasoning power at least sufficient to attempt the understanding of our circumstances.

Work of this kind is not usually compatible with the power of invention required to meet the material needs of civilisation. Accordingly we find that the inventor and designer is a man of different type from the abstract investigator. The abstract man must be intensely specialised; the inventor must have a wide acquaintance with the properties of all the materials with which he works, and must also have knowledge of the particular needs of the industry which he intends to improve. His work is quite different. It is true that the inventor may have to investigate part of the science of his subject for himself; he generally finds the sciences involved in any particular problem lacking in definiteness or information just where he requires it, and he often sets to work to determine the facts for himself. It thus generally happens that the science of any engineering subject is never fully developed by abstract investigation, and it usually requires the rise of a great industry to lead to the carrying out of the experimental determinations required for quantitative accuracy in working conditions.

That the work of invention is not usually performed by the discoverer and investigator of new sequences and laws is very evident from an examination of the records of the Royal Society. The Presidents of this great Society, which has had a vital influence on civilisation, are always very distinguished men of science, and almost invariably investigators and discoverers of the first rank. From 1820 to 1915 twenty-one Presidents have shaped the destinies of scientific development from the presidential chair, seated behind the great silver mace presented to the Society by Charles II. in 1662. Of those, however, only four could be considered to be inventors — Sir Humphry Davy, miners' safety lamp and electrolytic decomposition of the alkali metals; the Earl of Rosse, designer and inventor of the great reflecting telescope; Lord Kelvin, inventor of the mirror galvanometer, the syphon recorder, and other instruments for submarine cable work, and also the pianoforte wire deep-sea sounding instrument and the improved short needle mariners' compass, and many other electrical measuring instruments; and Lord Lister, the great medical investigator who applied the discoveries of Pasteur and Metchnikoff to the purposes of surgery, and thus saved many, many thousands of lives. The other Presidents, seventeen in number, include men of the highest genius, of whom may be mentioned Sir George Airy, Sir Joseph Hooker, William Spottiswoode, Professor T. H. Huxley, Sir George Stokes, Sir William Huggins, Lord Rayleigh, Sir Archibald Geikie, Sir William Crookes, and, at the present time, Sir J. J. Thomson. Among them they have largely shaped the science of to-day in astronomy, natural history, biology, physics, geology, chemistry, and the great modern development of the science of radioactive bodies and the study of gases under electric discharge *in vacuo*. These are, indeed, distinguished names of men who have rendered the world service which will never be forgotten. For some reason the list of Royal Society Presidents in the nineteenth century omits two of the most distinguished men of science—Michael Faraday and Charles Darwin—men whose discoveries and researches have influenced all modern scientific thought. Their names, however, are to be found among the recipients of the highest distinction of the Society—the Copley Medal, which has been awarded annually since the year 1731. This brilliant list begins with Stephen Gray in 1731, and ends with the name of Sir James Dewar in 1916—174 names in all. Of these most distinguished men of scientific discovery only twelve can be considered to be inventors. They are: (1753) Benjamin Franklin, (1759) John Smeaton, (1796) Count Rumford, (1794) Professor Volta, (1805) Sir Humphry Davy, (1838) Carl Frederick Gauss, (1844) Carlo Matteucci, (1860) Robert Wilhelm Bunsen, (1868) Sir Charles Wheatstone, (1883) Sir William Thomson, (1902) Lord Lister, and (1916) Sir James Dewar. Curiously enough, the great name of James Watt does not appear in any Royal Society list of awards.

As an interesting matter of mere fact it is evident that a great discoverer and investigator is not necessarily an inventor; some are, but they are few in number. It is an error, then, to assume, as many scientific men do, that men distinguished in abstract research also possess

the power of practical design and invention. It is also an error to assume that the evolution of a great invention follows the course usually considered true and logical; that is, that the abstract scientific investigator discovers the phenomena and determines the laws, and the inventor and designer applies these laws and facts to the practical work. It is also assumed that the original discovery on which the invention rests requires a higher order of mind than that required for the application of the laws when so discovered. It is stated by many scientific men that inventors, designers, and manufacturers are culpably ignorant in neglecting the application of laws already known immediately to practice. The assumption is that application is easy and rapid, while discovery is slow and difficult. A short examination of the course of development of several leading inventions will show the true facts and explain the reason of the frequent disappointment of scientific men in their efforts to apply their science to practice.

Faraday made his great discovery of the induction of electric currents by magnets in the year 1831, and he endeavoured to produce a magneto-electric machine, and he describes several attempts in his Researches. He appears to have nearly approached a successful working machine in the apparatus which he thus describes: "A disc of copper, twelve inches in diameter, and about one-fifth of an inch in thickness, fixed upon a brass axis, was mounted in frames so as to allow of revolution, its edge being at the same time introduced more or less between the magnetic poles. The edge of the plate was well amalgamated for the purpose of obtaining a good but movable contact, and a part round the axis was also prepared in a similar manner. Conductors or electric 'collectors' of copper and lead were constructed so as to come into contact with the edge of the copper disc." Electric currents were obtained from this apparatus, but the first magneto-electric induction machine which reached the market was the invention and design of an Italian, Pixii. It appeared in the year 1833. In it horse-shoe magnets were rotated on a vertical axis, so that the poles passed close to the soft iron core ends of two bobbins mounted above it. A commutator collected the current and caused it to flow in successive impulses in the same direction. This machine was superseded in a short time by Clark's machine, in which the magnets were stationary and the bobbins revolved; the commutator was also improved. The first machine, however, to produce the electric light by magnets was known as the Alliance Company's machine. It was produced in 1849 as the result of the modification of Clark's invention by M. Nollet, Professor of Physics in Brussels, and a workman, Van Malderen. In 1856, Werner Siemens invented and designed a new machine of much greater power for weight and bulk; the leading advance consisted in a shuttle-wound armature of small diameter, but considerable length. Later, Wilde, of Manchester, greatly improved the Siemens machine by substituting soft iron electro magnets to produce the field and exciting the electro-magnets by a smaller separately driven magneto machine. In 1860 the ring type of armature and winding was invented by Pacinotti. This was later developed by the Belgian engineer, Zénobe Gramme, and became known as the Gramme ring machine.

So far the machines proposed used permanent magnets, either to generate current to excite the field magnets or to produce the field itself directly. About 1866–67 Varley, Wheatstone, and Werner Siemens separately, but almost simultaneously, proposed to use the current generated by the machine to magnetise its own field magnets, and this proved to be a principle of first-class importance. The machine depended upon the residual magnetism of the soft iron magnets to enable it to start up, and although the flow was feeble at first, it speedily increased as the current passed through the field magnet coils. Such machines were called dynamo-electric machines, as suggested by Werner Siemens. Then followed the differentiation of *series-wound* and *shunt-wound* dynamos; in the first the field magnet coils were heavy and carried the whole current, and in the second only a portion of the current was so applied. The first application of the self-exciting principle of Varley, Wheatstone, and Siemens was made about 1870 by the English instrument-maker, Ladd. The Gramme dynamo, introduced in 1870, became very successful; it has been extensively used.

Thus thirty-nine years elapsed between the great discovery of Faraday and the invention, design, and application of a moderately successful machine embodying Faraday's fundamental principles. Many inventive and highly instructed minds had shared in solving the difficult problems presented, and the science of the subject was simultaneously studied by many technical experts. Much yet remained to be done; the dynamo was not yet self-regulating, and it was

by no means evident how this could be best accomplished. In this connection I may be permitted to mention an interesting fact. In the year 1883 Lord Kelvin (then Sir William Thomson) had a gas engine of my invention and design fitted up in the University Laboratory to drive a Siemens shunt-wound dynamo for the supply of electricity for lighting his house in the University grounds with the then new Edison incandescent lamps. Lord Kelvin took a great interest, and himself designed the house switches and the special regulating device which he attached to the dynamo in order that the current supplied to the house, which varied with the number of lights in use, should have a nearly constant voltage. Lord Kelvin explained the device to me, and I frequently saw it in operation. To prevent change of voltage with alteration of the output of the dynamo he arranged a variable resistance for the control of the shunt current passing to the exciting field. This resistance consisted of a small wheeled conductor arranged to travel up and down an inclined rail; at each position the appropriate resistance was inserted in the field circuit. The operation was mechanical and very ingenious: a shallow circular vessel was rotated at a low speed; it contained a somewhat viscous oil. In the oil two toothed wheels, geared into each other, were immersed, and a spindle from one of the wheels was carried up to a centre from which the wheels and their spindle and frame were hung; the wheels were drawn to one side of the rotating vessel by a light spring, and a solenoid operated by varying current was arranged to oppose the spring action. When current varied the wheels moved to one or other side of the vessel; when in mid position the viscous oil acted as if gearing into the outer teeth of both wheels, and so the spindle was held stationary; when the wheels passed to one side or the other the outside wheel acted as if geared by the oil to run in one direction to lift the rolling switch and diminish the resistance in the exciting circuit; when in the other direction the switch rolled downwards and increased the resistance. Thus the dynamo supplied the house with varying current to suit the number of lamps in use as required. The apparatus interested me very much, and it worked quite well. Lord Kelvin was delighted with it, and it was used for some years.

Very soon, however, the compound-wound dynamo was introduced, the invention again of Varley and others, and in this improvement the field was supplied with a certain proportion of series winding as well as shunt. The proportion was so arranged that, given constant speed of rotation, the current varied as required, and the voltage of the supply remained nearly constant. The theory of compound winding has also received great attention, and it is now thoroughly understood. In 1883, however, the simple device of compound winding was not an obvious one to the highly-trained scientific mind of Lord Kelvin, as is shown by his use of the ingenious but cumbrous apparatus which I have described. That is a very interesting circumstance which proves that the slow development of the dynamo from Faraday's time was due to inherent difficulties which could not be solved at short consideration by even the greatest of scientific men. It appears to indicate that the step by step progress by trial, testing of results and trial again is a necessary process in the production of invention as well as in the discovery of new facts. Thus, in the year 1884, which saw the introduction of the self-regulating compound dynamo, fifty-three years had passed since Faraday's discovery of the fundamental action on which the great modern industry of electric light and power is now firmly based. Faraday died in 1867, seventeen years before the more advanced application of his work. The whole great structure springs from Faraday's work; the full realisation, however, occupied hundreds of acute inventors and investigators for many years. The application of science to industry was undoubtedly a slow process in this instance. Here, however, we are fortunate in tracing the industry from the discovery of the fundamental fact that a magnet moved relatively to a coil produced an electric current.

In other great inventions the same slow process of development is always found; the steam-engine from Newcomen to James Watt and on to Parsons, followed the same course of step by step improvement, but in this case the engine came into existence before any true theory of the nature of heat was arrived at. These steam inventions belong to a great class in which it may be truly said that the engineer-inventor produced machines which it became the function of the scientific discoverer to explain. What would logically be considered the fundamental science did not exist in either Newcomen's or James Watt's time. Heat was supposed by most scientific men to be material, and chemists revelled in the use of the "phlogiston" theory to account for flame and the effect of many chemical actions. Watt died in 1819, and Carnot did not publish his great paper

on the Motive Power of Heat till 1824, so that Watt died before the beginning of thermodynamics as a science. Even Carnot's work did not throw any very clear light on the relationship of heat to mechanical work, because his reasoning was consistent with the caloric or material theory. On Carnot principles of that date the amount of energy to be obtained from any given amount of heat might be of any value, depending only on the temperature fall. The idea of the mechanical equivalent of heat required the abandonment of the material theory, and, strangely enough, Lord Kelvin, who studied Carnot, was the latest of the great physicists of the nineteenth century to accept Joule's results as announced by him about 1841.

The study of steam and other heat engines apparently gave rise to the science of thermodynamics, which has given us, perhaps, the greatest generalisations known to science, applicable equally to motive power, physics, and chemical action. The first and second laws have been and are invaluable in nearly all physical and chemical reasoning.

Parsons was fortunate in finding thermodynamics fully understood when he began in 1884 his great work on the steam turbine; but with all the help of abstract laws, he found much to investigate in the flow of steam-jets which had not been understood till the time of Laval and Parsons. Even with all the knowledge of the time, Parsons required from 1884 to 1898 to work through the great difficulties of his subject. Here the investigation had to be made on what he as an engineer had successfully produced.

The science of thermodynamics is thus in one of its sides an explanation of the laws of operation of engines already in existence. In the case of the electric light, the dynamo sprang from the scientific discovery of Faraday. In the case of the steam-engine the science sprang from the reasoning on the facts of practice. Here, too, the invention has been of the step-by-step constant invention, design, construction, and trial, and equally constant investigation of the facts revealed by the numerous tests. No royal road is here which would enable the scientific discoverer at once to apply his discoveries to practice.

The long-continued action of many minds is also characteristic of the brilliant progress of the internal-combustion engine. In this case also a considerable part of the early development occurred before the existence of any science of thermodynamics. So far back as 1680 Huygens proposed to use the explosion of small charges of gunpowder in order to obtain motive power, and Papin in 1690 continued his experiments without success. The idea was simple; a small quantity of gunpowder was exploded at the bottom of a large cylindrical vessel filled with air, and the expanding gases expelled the air through lift-valves, so that, after cooling down, a partial vacuum was caused in the vessel. This reduction of pressure was utilised to actuate a piston, but too little power was obtained, as in a paper published in Leipzic in 1688, Papin stated that: "Until now all experiments have been unsuccessful; and after the combustion of the exploded powder there always remains in the cylinder one-fifth of its volume of air." An explosion engine using inflammable vapours was described in an English patent by Robert Street in 1774. Here the explosion of a mixture containing inflammable vapour and air drove the piston directly. Many attempts of this kind were made, and as early as 1817 Professor Farish, in Cambridge, showed an explosion engine in operation on his lecture table. In 1820 also the Rev. W. Cecil, M.A., read a paper before the Cambridge Philosophical Society, in which he described a hydrogen engine, and showed it in action operating by the production of vacuum after explosion. Even the first definite and accurate proposal to compress the charge before explosion was made by William Barnett in 1838, some years before Joule's first paper read to the British Association on the Mechanical Equivalent of Heat.

Internal-combustion engines were thus proposed long before the inventors could have availed themselves of thermodynamics. In these inventions only comparatively simple observations were necessary to produce a working machine. Obviously a gaseous explosion by expansion exerts considerable power, so the early inventors made inflammable mixtures and produced at first explosions starting from atmospheric pressure. They found such explosions weak, and sought to obtain higher pressures and more power by compressing the mixture before ignition. A whole series of inventions sprang from this idea, such as those of Beau de Rochas, Otto, Clerk, Robson, Atkinson, and Diesel. The first commercially successful compression engine was that of Otto in 1876—twenty-eight years after Barnett's proposal. The development of the idea continues to the present day, and now, in 1917, some seventy-nine years after the proposal of compression, we are still inventing and designing new and better internal-combustion

engines, and shall certainly take many years longer without approaching finality. From about 1877 to the present time, however, the science of thermodynamics has been fully applied, and the practical experience of the designer has suggested lines of scientific research into the phenomena of combustion and flame, so that quite a considerable body of abstract science has arisen around these engines which would not have come into existence without the stimulus of a great industry. Many abstract physicists and chemists have contributed to the discoveries made in connection with the working fluid, but the engineers engaged in the design and construction have also thrown great light upon the scientific side. Thus, in the experimental development of the explosion gas engine it was quickly found that the properties of gaseous explosions had not been thoroughly investigated by the abstract investigator. In 1876, when I began work upon the subject as an inventor and designer, I could find no record of experiments made upon the maximum pressures attained by varying mixtures of coal gas and air mixed at atmospheric pressure and ignited by electric spark or flame. The only experiments in existence were those of Bunsen conducted in small glass tubes. Bunsen determined the maximum pressure of the explosion by loading a glass plate valve, closing the end of the tube by lever and weight, like the safety valve of a steam boiler. The maximum pressures so obtained were subject to great errors due to the inertia of the weights and to the very short duration of the maximum pressure in his small glass vessels. Mallard and Le Chatelier made experiments with a better, although still very imperfect, indicator, and with somewhat larger vessels; the records, however, were not sufficiently good to supply the data necessary for studying the explosions within gas engine cylinders. Accordingly I prepared apparatus consisting of a cast-iron cylinder, 7 in. diameter and 7 in. long, of a capacity similar to that of a gas engine compression space, and fitted it with an accurate indicator of the Richards type. By this apparatus I was able to investigate the times and pressures of gaseous explosions under various conditions of mixtures, initial temperature, and pressure. These experiments were published in 1886, and proved most useful to engine inventors and designers. At the same time they brought to light many important facts interesting from the purely scientific standpoint. One discovery was that the rate of explosion in the closed vessel experiments was much slower than that found in the engine cylinder with moving piston for precisely similar mixtures. The complete explanation of the cause of this difference was ultimately found, many years later, simultaneously by Professor Hopkinson, of Cambridge, and myself in the course of different types of investigation, Hopkinson using a fan in a closed vessel and my experiments being made in an engine cylinder with piston actuated and charged in the ordinary action of the engine. The experiments proved the existence of a residual turbulent motion which lasted throughout the whole compression stroke and was due to the velocity of the charge in passing through the inlet valve, which amounted to from seventy to one hundred miles per hour. In my experiments I caused the engine igniter to remain out of operation and held the valves closed, so that the mixture was compressed three times before ignition; this allowed a pause of one second between the beginning of the suction stroke and ignition, instead of one-third of a second, the usual interval in the ordinary running of the engine. The rate of ignition after the rest of one second was about one-third of the normal value, and corresponded closely to the rate of the same mixture in the closed vessel. Hopkinson experimented in a closed vessel fitted with a fan, and he found that the rate of ignition increased with the increased speed of rotation of the fan.

It was also necessary for the study of the indicated thermodynamic efficiency of these engines to learn the instantaneous specific heat of the ignited gaseous mixture which is in a state of flame, the mean temperature of the flame ranging from nearly 2000° C. at the beginning of the stroke to 1000° C. at the moment of the exhaust valve opening. The problem is one of considerable difficulty, as the high temperature only lasts about one one-hundredth of a second, and it is necessary to determine the instantaneous specific heat of the mass of flaming gases at or about one-fiftieth of a second intervals during the expansion stroke. In this I succeeded by subjecting the flame to successive compressions and expansions in the cylinder by the action of the piston, and studying the work area produced by expansion in the short period, and deducing the law of heat loss from successive expansion and compression lines. The results of this investigation were published at the Royal Society in 1906, and at the Institution of Civil Engineers in 1907. This is the

first method discovered of dealing with the properties of flaming gases at intervals so short as one-fiftieth of a second, and I mention it to show how the work of engine invention and design necessarily suggest new lines of investigation not previously dealt with by the abstract investigator. In all the great inventions on which our civilisation depends the process of development has led to the alternate practical trial of the invention and the investigation of the phenomena brought to light by the trials.

Science is thus indebted to industry for its stimulus and progress in many of its achievements, and industry is indebted to science for much information of the fundamental laws necessary for clear thinking in invention and design.

The application of internal combustion in the form of the petrol engine to motor-car and motor vehicle work, and the great recent extension of the use of such engines for the purpose of aeroplanes, has also revealed new problems which for their solution require both abstract discoveries and concrete inventions. The scientific investigation of the conditions of operation, and the invention of better modes of operation, are now proceeding side by side at a rate greatly accelerated by the necessities of war. This is true also of the heavy oil types of engine such as the Diesel as used for marine work.

This alternate action and reaction of invention, design, and scientific discovery is evident in all considerable inventions which always have a long history of development. In attacking the difficulties of the steam engine Watt was well informed of all the science of the day, and the one item of information from a purely scientific source was that of the latent heat of steam, the discovery of Black, of Glasgow University; but Watt found the existing knowledge of the properties of steam insufficient, and part of his work consisted in investigating for himself by actual experiment on saturated steam under different conditions of temperature and pressure. Steam engineers as inventors and designers are now deeply indebted to pure scientific research by distinguished physicists from Regnault to Callendar, but in the early days many of their data had to be obtained by themselves. This applies also to the great modern development of the steam turbine; much of Parsons' work consisted in accurate experiments on the flow of steam through blades of varying configuration, and his great success in obtaining economy superior to the reciprocating engine depended on his investigations of methods of intensifying vacuum by the use of steam-jet ejectors.

This is also true of the development of flight. Ideas were plentiful hundreds of years past: Leonardo da Vinci made many experimental wing models, and attempted what we should now call gliding experiments, but nothing practical came of it till the time of Langley in America. He experimented on large steam-driven models started from a large barge and flown over a lake. He obtained actual flights, but the model fell into the lake and was damaged, so that the experiments were laborious and slow. Definite progress was made by the gliding experiments of Lilienthal and Pilcher, which sadly terminated in the death of both experimenters. Maxim carried the demonstration a stage further, but real flight of heavier-than-air machines was not attained till the petrol engine was developed to a sufficient extent to enable a light engine to be mounted on a glider. This was accomplished by the brothers Wright in America about 1906, and they courageously carried out the early experiments which led to the successful aeroplane of to-day. In this invention also the science of the subject rapidly developed after the demonstration of the practicability. What purely scientific men considered before 1906 as a possible gymnastic feat, under the combined and alternate influence of practical experiment and scientific and mathematical research, has become a reliable fighting and travelling mechanism, whose use can be taught to thousands of young men in the course of a few months' training. In this country the progress of the aeroplane has been due to the combined scientific and experimental work of the Advisory Committee for Aeronautics; the National Physical Laboratory; the Royal Aircraft Factory, and numerous able scientific young men now in the Royal Flying Corps, and private experimenters and designers. Many of these brave men have lost their lives in the development of this wonderful invention; among them we deplore the death of Captain Busk and Captain Lucas, both of Cambridge University, in the pursuit of their duty to their country. Both investigators were brilliant young scientific men, and they accomplished excellent work to keep their names in remembrance. In this development, too, practice and examination of the results have gradually led to the establishment of the scientific facts of the aeroplane, both physical and mathematical.

While on the subject of the contribution of mathematical science to the development of inventions, it is necessary to call attention to the somewhat surprising lack of appreciation

which some very distinguished mathematicians have shown of the conditions of practice and the limitations of mathematical prevision. It is shown in their well-known contempt for experimental physics as compared to mathematical physics. The man of intense mathematical mind feels that until scientific facts can be deduced from first principles originating in the sense of reason in the human mind, the particular science must be stigmatised as "empirical." Mathematical science is not empirical; its conclusions are absolutely true, that we sometimes accept without proper examination of why such reasoning appeals so powerfully. It seems to me that the reason is simple. Mathematical truth is accurate because it is defined so. The deduction, however abstruse, is contained in the definition of certain abstract conditions. Mathematical conditions are carefully defined to begin with, and the investigators discover further relationships which flow from the original definition. Such reasoning supplies the best and highest examples of the deductive method of reasoning, and wonderful and most useful discoveries have been made without appealing to experiment. The discovery of logarithms by Napier was most surprising, considering the condition of other knowledge three hundred years ago, and it is still more surprising if the discovery was really made to enable Napier to accomplish the apparently complicated calculations necessary to arrive at the number of the beast, as is alleged.

This intense introspection seems, however, at times to blind the mathematician to much of experimental interest, and it led its victims into a curious position well stated by Professor Schuster in his valuable book on the progress of physics between 1875 and 1908 as follows:—

"The detachment of the theoretical study of Physics, as it was conducted at Cambridge, from the experimental presentation of facts, led in some cases to a remarkable antagonism to ocular demonstration, which is illustrated by a characteristic incident. Clerk Maxwell, who possessed an innate desire to see what he could with his own eyes, had taken considerable trouble in cutting and grinding a plate out of a doubly refracting crystal to show conical refraction. The experiment is difficult; and, delighted at its successful accomplishment, Maxwell met one of the mathematical teachers of the University. 'Would you like to see conical refraction?' asked Maxwell. 'No,' replied Todhunter, 'I have been teaching it all my life, and I do not want to have all my ideas upset by seeing it.'"

Professor Schuster assures us that this was not jocular; from other statements it appears to have been a characteristic attitude of Todhunter; and some other mathematicians—a well-known professor, for instance—distinctly adopted the same attitude in a slightly different form at a joint meeting of physicists and engineers at the British Association in Sheffield in 1910. He considered at that date that no further flights with aeroplanes should be attempted until the mathematicians had completely deduced the laws of aeroplane stability by discovering the solution of certain equations. He stated that the problem of flight presented separate fields of investigation for those who worked on paper, in the laboratory, and in the air itself. It was important, he thought, that each should concentrate his work in the field for which he was most fitted, and develop it to its ultimate conclusions. There need, therefore, be no serious antagonism between different investigators if each would be content to keep to his own line of work. What he complained of was the misuse of mathematics by engineers, and their slipshod and inaccurate methods of reasoning.

In every advance in engineering, he claimed that mathematical treatment became necessary, and this necessity was recognised abroad. Was it not desirable, therefore, that more facilities should be provided for those working on paper and in the laboratory; and though the ultimate appeal must be to the practical man, he contended that such a course as he proposed would be both cheapest and best. It would be cheapest because mathematicians could be obtained at less price than a mechanic, and it would be best because it would avoid the present frequent deplorable loss of life. So long as anything remained to be studied, those who persisted in flying incurred avoidable risks, and were foolhardy rather than courageous. If experiments would put an end to this working in the dark, they would, he contended, be most conducive to the welfare of the practical man, since it was he who was killed. Had not the practical man already got his hands full with other work? Even as regarded stability, the tests should be made on models, and not with man-carrying machines, and at present there was no need for further demonstrations of the mechanical possibility of flight. Warning should be taken from the history of navigation as described by Elgar, and we should not add further to the terrible death-roll till no stone was left unturned in probing the mathematical theory of stability to the bottom.

This distinguished mathematician obviously shared Todhunter's dislike of engineers' "slipshod and inaccurate methods of reasoning"—that is, of experimental work, and the use of empirical formulæ representing the results of experiments. Mr. Lanchester's work is specially mentioned by him in this connection, and yet Lanchester's alternately experimental and mathematical work from 1897 enabled him to obtain much accurate scientific knowledge. useful equally to the aeroplane designer and suggestive to the abstract mathematician desirous of attacking such problems.

The thinking of the mathematician would be quite sterile if he confined himself to his desk and chair, and endeavoured to evolve the complicated facts of nature out of his own consciousness. Had the Professor's advice been taken in this case the surprising progress of the last ten years would have been impossible. Mathematics without the vivifying stimulus of experiment and practical flight would certainly have failed. As things are, many instructed mathematicians and physicists have co-operated with the practical designer and inventor to produce the existing considerable body of scientific and practical knowledge.

The work of the mathematician is most useful, and it is necessary to success equally in Discovery, Invention, and Design, but it is useless alone—it has never performed, and cannot perform, the marvels of prevision claimed for it by some of its followers.

With regard to chemical discovery and invention, science has followed the same course. Before the existence of any chemical science in the modern sense, mankind for ages conducted many manufacturing processes, such as soap-making, glass-making, iron and copper smelting, sulphuric acid manufacture from green vitriol—hence the old name "oil of vitriol"—brewing and distilling alcohol from many sources, and wine growing and making, dyeing, and so on, all of which involved chemical operations. Alchemy, too, led to many experiments which produced a knowledge of chemical sequences. Thus the earlier chemists of modern type found a mass of information ready for study; their work consisted in studying processes already in existence, and this led to the overthrow of the doctrine of phlogiston by Lavoisier, and the explanation by him of combustion and classification into acids, bases and salts about the middle of the eighteenth century. Lavoisier's work also established the law of the conservation of mass and the law of constant proportions in chemical compounds. His work in chemical theory was so highly esteemed that Wurtz, an eminent French chemist, in a History of Chemistry published about 1870, begins with: "Chemistry is a French science. It was founded by Lavoisier of immortal memory." In one essential matter, however, the true definition of the term "element" as a substance found to be incapable of further analysis, the British scientific man Robert Boyle, preceded Lavoisier, and he has been also described as "the father of chemistry." Boyle also discovered the law of the isothermal compression and expansion of gases.

In 1808 John Dalton introduced the atomic theory, and enunciated the law of multiple proportions without which modern systematic chemistry could not exist. Avogadro's hypothesis, "Equal volumes of gases, simple or compound, contain under the same condition of temperature and pressure the same number of molecules," was introduced in a paper published in 1811, but it was not accepted generally by chemists until explained by Cannizzaro in 1860. About this time the physical properties of bodies were studied as well as chemical reactions and relations, melting points, boiling points, specific gravities, and rotation of the plane of polarisation were determined. In this connection may be mentioned the interesting discovery by Pasteur, made while he was a very young man, that in compounds which rotate the plane of polarisation to the right there exist many compounds of the same chemical compositions which rotate it to the left, such compounds differing only in the arrangement of the atoms composing the molecule in the sense that the reflected image in a glass differs from the object reflected. The law of Dulong and Petit, that the specific heat of elementary solid bodies varies inversely as the atomic weight, proved most important. The original discovery by Sir Humphry Davy of the electrolytic decomposition of the alkalies and alkaline earths producing new metallic bodies was followed later by Faraday's determination of the quantitative laws of electrolysis.

The knowledge of the physical and chemical properties of the elements which had thus accumulated led to the wonderful discovery of Newlands in 1863, followed by that of Mendeleeff in 1869, that the elementary bodies when arranged in order of atomic weight showed a distinct periodicity of properties, so that the elements could be divided into groups of eight of ever-increasing atomic weight with constantly recurring properties. This variation is shown most clearly by Professor Richards in curves of the

properties of thirty-five solid elements. The properties chosen are melting points, co-efficients of expansion, atomic volumes, and compressibilities. So accurate is this periodicity that Mendeleeff predicted the existence of unknown elements because of certain gaps in his tables; and the elements were discovered later, and they possessed the properties proper to their place. The existence of this periodicity suggests a common origin for all the elements, that the elements are in fact built up from some one substance of low atomic weight. This hypothesis was somewhat crudely stated by William Prout, a chemist and physician, at the end of the eighteenth century.

The discovery of radioactivity by Becquerel, and the separation of radium salts by Madame and Professor Curie, supplied Rutherford, Soddy, and Ramsay with the basis for investigations which proved the existence of atoms, or, rather, so-called atoms, which disintegrate spontaneously and form many other bodies. This, with the brilliant work of Sir J. J. Thomson, proved the existence and properties of a unit body called the electron, which body could be detached from any gaseous atom by electric discharge *in vacuo*, and at once suggests that there is some truth in the idea of the ultimate unity of all matter. This hypothesis may yet throw startling light upon the ultimate constitution of matter, the nature of electricity and the nature of mass, and even give a key to the nature of gravitation at present so entirely inexplicable. Sir William Crookes, as early as 1886, discussed the strange periodicity of the elements in connection with a possible unity of origin at a meeting of the British Association.

Chemistry is thus rapidly evolving laws of a most general character, and finding unity in the hitherto bewildering complexity of its sequences.

In this work the progress of spectrum analysis and its application to the sun and stars enables the chemistry of our planet to be applied to other worlds outside of the solar system. Indeed, so interchangeable is general knowledge that the elementary gas, helium, was known spectroscopically as existing in the sun long before it was detected on the earth. Its detection by the late Sir William Ramsay in the mineral clevite, and its subsequent discovery by him as one of the decomposition products of the emanation from radium, forms one of the romances of science.

So far, then, the progress of chemical science displays the same characteristic of abstract investigation leading to the better understanding of existing chemical phenomena and processes by tracing the particular reactions involved and the further work of the discovery of new reactions and decompositions; the effects of mass action, catalysis, electric decompositions and combinations; many of which abstract discoveries have developed into manufacturing processes by inventors and engineers, and so given rise to the great modern electrochemical industry which gives us pure aluminium, copper, and other metals, as also soda and many new products such as calcium carbide and other compounds. Here, too, the history of discovery and invention resembles that of the physical and mechanical discoveries and inventions already discussed.

The marvellous progress in the study of biological problems has been produced by similar action and reaction of abstract investigation suggested generally by practical experience and the testing of hypotheses flowing from the investigation. This is finely shown in a brilliant address recently delivered at the University of Leeds by the distinguished English surgeon, Sir Berkeley Moynihan, where he traces the course of the great modern developments in surgery. The discoveries in antiseptics began, he tells us, with Latour, who established in 1836 the living character of the yeast cells by which fermentation was produced. This was confirmed by Pasteur in 1856, who showed that putrefaction and fermentation were the result of living particles, and that for each type of fermentation a specific particle was necessary. He proved the existence of "aërobic" and "anaërobic" organisms, and showed the error of the old idea that oxygen caused putrefaction. Lister made the forward step that wound discharges were similarly caused, and he applied his deduction to surgery with the success which all know. Moynihan traces the history of many important operations, and clearly shows the interdependence of abstract investigation and surgical practice. He sums up this question very clearly as follows: "A discovery is rarely the work of one mind. It is one observation added to another that makes the supersaturated solution from which the crystal of truth at last precipitates. Lister never ceased to give credit to Pasteur for his share in the work that led finally to the development of the antiseptic method. The exploratory work, the pioneer work—all that was original—was done, therefore, by a French observer and an English surgeon."

Discoverers, like inventors, may investigate

the nature of known facts, facts which have been brought to knowledge by the age-long struggle of mankind to obtain subsistence from an unwilling earth and security of life amidst dangers of nature and man. The discovery may consist in the orderly establishment of some invariable sequence common to a wide class of phenomena; such were the discoveries of the earlier systematic chemists beginning with Lavoisier. The laws of motion, of gravitation, of electricity and electro-chemical action, are all of this type. Or the discovery may bring to light new phenomena never known to man, such as Harvey's circulation of the blood, Jenner's inoculation for smallpox, and the whole series of modern preventive inoculations, the existence of new elements, the discovery of argon by Lord Rayleigh and Ramsay, for example, the new class of substance proving the existence of a disintegrating atom. Or the discovery may be mathematical, such as Napier's logarithms, Newton's fluxions, etc.—discoveries, as I have pointed out, of abstruse consequences of rigid definitions depending on the innate use of reason of the mind.

All these matters are the result of investigation intended only for the purpose of arriving at the truth with regard to the world around us, and, as important, the truth as to ourselves. We are the instrument through which truth and facts appeal, and our reactions require study as careful as that given to the calibration of our apparatus.

Invention, like discovery, begins with a consideration of known facts, but its object is to produce a given result of some specific material utility to mankind; the inventor is also an investigator, but he considers first those facts of science as well as ordinary knowledge which bear on his problem. The inventor's object is to do something required by mankind to aid in the struggle for existence.

Thus, the advent of the industrial revolution in the middle of the eighteenth century began by the use of "sea coal" and the increased production of iron. Coal-pits required to be kept dry, and thus a demand arose for a "fire engine"—that is, a steam engine operated by fire. This was partly satisfied by Newcomen, and James Watt's inventions extended the scope of the steam pump, and ultimately led to steam locomotion on land and water. The inventors' object here was to produce a new machine capable of actuating factories, railways, and ships. The facts required to produce motive power by steam and fire were few and simple, and the conditions of economy were arrived at by Watt without any very elaborate investigation of abstruse phenomena. The work of the engineer and inventor results in the creation of practicable working machines able to perform specific tasks; consequently they press on with all speed on concrete invention, design, and production, without turning aside to understand all the phenomena which appear during their work.

It is their task to produce, not necessarily to understand.

It is the task of the scientific investigator to understand, elucidate, and explain as far as possible the fundamental principles which appear as the result of the operations of the machines now in existence.

Both discoverers and inventors are impelled by the intense desire to produce new things and understand new facts and laws. Neither is actuated by pure commercial instinct; incidentally both, as good citizens of the world, naturally desire a reasonably secure financial position; but the love of money, which is said to be the root of all evil, could not furnish impetus sufficient to maintain either through the vicissitudes of the laborious life necessary to attain the end. To succeed here there must be entire and long-continued devotion to study and experiment inspired by an enthusiastic appreciation of the new possibilities.

Science is succeeding admirably in discovery, and important inventions are evolved slowly by the labours of great numbers of men who may encounter failure after failure through many generations, but yet inventor follows inventor like soldiers in battle until success comes at last. Great inventions are never the work of one man. To adopt Sir Berkeley Moynihan's beautiful simile to invention: "Invention is rarely the work of one mind. It is one observation added to another that makes the supersaturated solution from which the crystal of inventive truth precipitates."

The Chairman (Alan A. Campbell Swinton, F.R.S., M.Inst.C.E., M.I.E.E., M.I.Mech.E.), in proposing a vote of thanks to Sir Dugald Clerk for his very interesting and instructive lecture, said that papers of the kind in question gave one a great deal to think about, as did of course all matters in connection with discovery and invention. He did not know if it had ever occurred to those present why it was that printing took such a long time to come about. The ancient Assyrians used printing of a kind; they had inscribed rolls with which they printed upon clay. That was more than two thousand years ago, and

yet it was not until the middle of the fifteenth or sixteenth century that printing in its modern sense was introduced. The lecturer had pointed out many of the difficulties that impeded the progress of invention, and it had occurred to him that possibly the reason why printing was not in use earlier was because there was no paper. He did not know if that was the true explanation, but of course as long as all writing had to be done upon parchment, and that parchment was very scarce, there was no need for printing, because the small amount of parchment available could easily be covered with writing by hand. It was well known who invented printing, but as far as he was aware, the inventor of paper—which was in many ways a much more complicated invention—was an entirely unknown individual. Again, in many cases invention was impeded by want of proper workmanship. He had recently been reading some letters of James Watt that had only lately been published, and he found that in the year 1784, almost exactly one hundred years before the invention of the turbine by Sir Charles Parsons, James Watt understood perfectly all the requirements for making a steam turbine. He discussed the matter at great length in a letter he wrote to his partner Boulton, but he was prevented from doing anything in the matter by the imperfections of the workmanship that was possible at that time. He wrote: "In short, without God makes it possible for things to move 1,000 ft. per second, it cannot do much harm." By that he meant that a particular steam turbine someone was then proposing could not do much harm in the way of competition with his (Watt's) engine. That was entirely a difficulty of workmanship. The workmen of that time could not make machinery sufficiently accurately to work at high speeds without undue friction. There was not much cause for surprise in that, because James Watt himself, in his earlier engines, had to use cylinders of iron, which were not bored—nobody could bore them—but were beaten into shape, and he thought himself very lucky when the piston fitted the cylinder within one-eighth or one-quarter of an inch. Sir Dugald Clerk had mentioned Faraday, and in that connection he might mention some of the difficulties that Faraday had to contend with. Most of his experiments upon induction were performed with what was called insulated wire. If one wanted some insulated wire nowadays—or, at any rate, before the war—one just went to a shop and bought some; but Faraday could not do that. He had to insulate his wire himself, doing it laboriously with worsted and tape. When one had to make all the essential parts of an apparatus oneself, even down to the wire, it naturally added very greatly to the existing difficulties. He was sure all the members had listened to the lecture with great pleasure, and that they would find it very instructive to read it again carefully. It was not a paper that could be fully appreciated at the first hearing, and he was sure it would repay further study, because there was a great deal of rather subtle information contained in it.

Sir Henry Trueman Wood said it gave him great pleasure to second the resolution, because it afforded him an opportunity of expressing his very keen appreciation of the great compliment the Society had paid him by establishing the "Trueman Wood" course of lectures, and also of thanking his friends, especially the present Chairman of the Council and his immediate predecessor, for all the kind remarks they had made about him. He thought those remarks were the outcome of a sympathetic friendship rather than of keen critical judgment, but they were none the less pleasant to the recipient. He was very glad that the first of the course of lectures had been delivered by Sir Dugald Clerk. Personally he had read a good deal about the history of invention, and sometimes he had written a little on the subject, but he had never come across so lucid an exposition of the essential difference between scientific research and practical invention as that contained in Sir Dugald's lecture. After Sir Dugald had elaborated his hypothesis he went on to demonstrate it by giving two or three most admirable illustrations from the history of invention to prove the truth of what he had said. The whole lecture was founded on a very favourite text of his own—that no man ever invented anything. That was absolutely true, although people did not seem to realise it. In one of the most popular modern histories of England the statement was made that in the year 1767 Watt invented the steam engine, but he never did anything of the sort. Again, in the volume of Reminiscences by one of our most charming and eminent men of letters that had recently been published, it was said that in 1770 Watt patented his engine, but the steam engine was at work fifty years before Watt ever saw one. But for the labours of his predecessors Watt would never have been able to do all the magnificent work that he did carry out. In conclusion, he wished once more to express his personal gratification that the course of lectures had been begun by his old friend, Sir Dugald Clerk, and to say that if Sir Dugald's lecture was followed by similar ones dealing with various branches of the application of science to human progress he really thought his services to the Royal Society of Arts, extending over nearly half a century, had not been altogether useless.

The resolution of thanks was carried unanimously, and the meeting terminated.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Standard Woollens.—Three or four months may be expected to pass before the new standard woollens for civil wear make their retail *début.*

Their composition and price rather than their external features are standardised, and purchasers will find a range of sound, sensible cloths such as nobody need hesitate to wear. The cost price may be called that of a high-class Saxony tweed before the war, or not much over one-third of the present price of such articles. The quality is not that of good Scotch tweed; but the approximation to old prices and old standards of durability should content reasonable people. Whether we are to have another kind of standard cloth for civil clothing will appear before long. Large quantities are to be made of a worsted serge which might, on occasion arising, be converted to khaki colour or be dyed blue, and which would be appropriate either for military or civil uses. The authorities have ventured upon a standard woollen for men, and an inferior standard for the cheaper clothes demanded for boys; but their discretion has not led them yet to the standardisation of fabrics for women.

Necessary Processes.—A more searching inquisition into the essentiality of particular trades is all too much to be apprehended, and it is already evident that crude judgments will not suffice. It was held the other day by a local body that calico-printing was not in the last resort indispensable, and that women might wear their blouses white. The truth is that calico-printing, like most other trades, is of varying degrees of utility. The process costs little, large bulks are treated in little time, and, in given circumstances, it effects a measurable economy. Printed cottons, having their surface variegated with colour, look fresh longer than white, and save in laundry expenses much more than the printing process costs. Printing is not necessarily an addition to the work of finishing, but is in some part a substitution for alternative processes. Psychological values count also for something in practical affairs, and it can be represented that any rapid and inexpensive treatment which goes to increase personal contentment with one's appearance is worth consideration at most stages of the progress of a war.

Children's Wages.—Advances of wages are made in compensation for the enhanced cost of living, but it is apparent that the excess does not all go in food. An employer of principally girl labour notices that hardly one girl in the mill is without rings on her fingers while at work. Like many others he is exercised in mind about the effect of very high wages upon the young. When a girl of thirteen, a few months out of school, has her 22*s.* wages raised to 24*s.* in consequence of a universal advance, he feels that children are being spoiled with money. Probably enough her father felt himself moderately well paid at no higher rate a few years ago. When children's labour ceases to be cheap, that is one reason for not employing it; but in present circumstances there is no opportunity of getting elder persons to replace them. By the time the over-paid youngsters are grown up there is no knowing what tastes they will expect to satisfy, and the outcome of a possible trade depression is not easy to foresee. A revolution in manufacturing conditions is almost the least that can be anticipated.

Export Business.—Projects for sending out collections of British samples to the foreign markets under care of an association or an official do not command much sympathy from textile manufacturers. They are not reluctant, at the proper time, to book export orders, but are rather more conscious than some of our zealots of the considerations involved in doing remunerative business. A maker of novelty goods finds his passport to favour in the preservation of the element of novelty, and when everyone has seen them their value evaporates. It is by the skilful confinement of his samples to the right channels that the producer is able to get anything for his labours. In the case of plainer goods the opportunity of doing satisfactory business turns upon fine points, which are all the more likely to be perceived after a skilled elucidation. Buyers and sellers appreciate the niceties of trading more fully than they are given credit for, and it is not to be supposed that they are in a position to accept half the advice that is offered them, or all the apparent opportunities of extending their trade.

The Colour Supply.—The British colour-making industry is admittedly not in the position that its best friend would like it to be in, and there is to be a further appeal for capital on behalf of the now great works at Huddersfield. The German combine, having included the sole remaining German independent concern, has raised its capital to £20,000,000. There must, in any event, be an intense commercial conflict to be waged in the dye trade, and the supreme desirability of putting the British works in the strongest position is felt strongly by consumers. Dyers are still without some of their most important staple colours, and they have to make shift with very limited supplies of colours that are nominally available. The position of the dye market is curious. Manufacturers are for the most part only ready to supply consumers under restrictions against resale. Dyes supplied to consumers do, however, filter into the hands of dealers. In one case which has been traced colour delivered at 9*s.* by the maker has resold at 36*s.* The first-named leaves a handsome profit upon the production, and if the second-hand dealings are merely in quantities of ten or twenty pounds, they are still sufficiently lucrative. The German companies, no doubt, aspire to profit handsomely from the temporary famine in dyes.

Historic Logwood.—During the war logwood has come back into use upon an astonishingly large scale—no longer in substitution, of course, for

madder, woad, and cochineal. Three hundred years ago dyers denied the use of logwood, until, the fact having been demonstrated, they set up the defence that its use bettered the dyeing. The dye figured in their books as fustic, and the totals went to show that they consumed every month more fustic than came into the country in a year. Suit was brought against the offenders by an informer, who turned the situation to his benefit by blackmailing the members of the Dyers' Company. The ingenious Hunt drew £4 a year from each member in consideration of delaying action from term to term. The history of crooked practices in the dye trade, it is to be feared, long out-dates the development of the coal-tar industry.

GENERAL NOTES.

South African Industrial Developments.—In his report for 1916, the General Manager of Railways and Harbours in South Africa states that the war has forced the people there to realise the extent of their dependence on oversea supplies. This consideration, coupled with the abnormal shortage of tonnage and the diversion of many European factories to the manufacture of munitions, has compelled South Africans to cater for their own requirements, with the result that many new industries have been established in the Union. Thus, an iron foundry has been started at Queenstown, and brass foundries at Benoni and Brakpan. A smelting plant for dealing with high-grade refractory ores has been established at Barberton. Large works for the manufacture of ammonia have been erected near Vryheid, the principal product at present being sulphate of ammonia. The company operating these works has a sulphuric-acid plant capable of producing 7,500 tons of acid per annum.

Production of Rum in Barbados in 1916.—Four distilleries were engaged during 1916 in the manufacture of rum in Barbados, writes the United States Consul for that island, and the production of rum for the year aggregated 315,359 gallons, against 185,952 gallons in 1915. Of the 1916 total 102,451 proof gallons were exported to other countries, and 1,937 proof gallons were issued for ships' stores, making a total of 104,388 gallon sent out of the island, or 69,851 gallons more than the exports in 1915. The increase in exportation is largely due to the war, practically the whole of this amount having been shipped to the United Kingdom and Canada.

Panama Canal Traffic, 1916-17.—The number of ocean-going vessels using the waterway during the year ended June 30th, 1917, was 1,876, of which 780 were British and 464 United States, the next most important nationality being Norwegian with 150, and then Chile with 99, Peru with 86, the Netherlands with 74, and Japan with 72. In the preceding fiscal year, 1915-16, the Canal was closed by a landslide for a considerable period, and the number of vessels passing through was only 787. The number of ocean-going vessels passing through the Canal in the first twelve months it was opened (August 15th, 1914, to August 14th, 1915) was 1,317.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

December 12.—Lord Charnwood, "Technical Training for Disabled Soldiers and Sailors." Surgeon-General Sir Alfred Keogh, G.C.B., M.D., F.R.C.P., Director-General of Medical Services, will preside.

December 19.—Professor J. Wemyss Anderson, M.Inst.C.E., M.I.Mech.E., Dean of the Faculty of Engineering and Lecturer in Refrigeration, University of Liverpool, "Science and the Cold Storage Industry." The Hon. Sir Thomas Mackenzie, G.C.M.G., High Commissioner for New Zealand, will preside.

Indian Section.

Thursday afternoon, at 4.30 p.m. :—

December 13.—D. T. Chadwick, I.C.S., "The Trade of India with Russia, France, and Italy." The Right Hon. Lord Islington, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

H. C. H. Carpenter, M.A., Ph.D., M.Inst. M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology. "Progress in the Metallurgy of Copper." Three Lectures.

Syllabus.

Lecture II.—December 10.—Causes of the decline of the copper-smelting industry in South Wales—Development of mining and smelting in Chili, Spain, and Portugal—Discovery and mining of the native metal in the Lake Superior district—Calumet and Hecla—Opening up of the Australian deposits—Entry of Arizona and Butte into the producing areas—Recent developments in Utah, Tennessee, Queensland, Tanganyika, Nevada, and Siberia.

Chief features of the development of modern copper-smelting practice in America. - Types of ore treated—Mechanically-rabbled roaster furnaces—Great increase in the size and capacity of blast and reverberatory furnaces--Application of Bessemer process to copper mattes—Development of pyritic smelting—Electrolytic refining—Manufacture of sulphuric acid from blast-furnace and roaster-furnace gases—Blast-roasting and sintering of

pines—Leaching—Flotation. Practice at Anaconda—Power production—Concentrator bins—Sampling mill—Gravity concentrator—Flotation concentration—Roasting practice—Reverberatory practice—The blast furnaces.

LECTURE III.—DECEMBER 17.—Converter practice—Refining and casting—Treatment of tailings—Flue-dust treatment—Extraction and purification of white arsenic—Electrolytic refining at the Raritan works—Production of commercial copper. Pyritic smelting at the Tennessee Copper Co.—Hydro metallurgy—Leaching at Chuquicamata—Present-day methods of extraction of native copper at Calumet—Treatment of mixed sulphide and oxide low-grade ores. Tendency of modern metallurgy.

Position of the industry in Great Britain to-day. Importance of copper-refining—Chief commercial varieties of copper, including tough-pitch arsenical copper—Need for exhaustive inquiry into the various aspects of the industry from the standpoint of Empire requirements, and of action to be taken on the basis of the results of the inquiry.

Papers to be read after Christmas :—

LORD LEVERHULME, "The Relations between Capital and Labour—Reasonable Hours, Copartnership, and Efficiency." W. A. APPLETON, C.B.E., Secretary of the General Federation of Trade Unions, will preside.

SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Commercial Intelligence Department, "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

ALEXANDER NEWLANDS, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in the British Isles."

FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." SIR ASTON WEBB, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

WM. FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

H. M. SURTEES TUCKWELL, M.I.Mech.E., "The Tata Iron and Steel Works" (India).

SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India."

HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-milling Industry of India."

SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana."

C. DU P. CHIAPPINI, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

The following series of papers has also been arranged, dealing with the Application of Scientific Research to the Development of particular British Industries :—

REGINALD S. CLAY, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry."

GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. LAWRENCE BALL, Sc.D., Manager o Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

SIR WILLIAM GEORGE WATSON, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." SIR ARTHUR D. STEEL-MAITLAND, Bt., M.P., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

January 17, February 14, March 14, April 18, May 30.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 5, March 5, April 30.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced) :—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

January 21, 28, February 4. At 8 p.m.

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: The Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m.:—

P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage." Two Lectures.

January 2 and 9.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 10...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor H. C. H. Carpenter, "Progress in the Metallurgy of Copper." (Lecture II.)

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m.

Geographical Society, Burlington-gardens, W., 8.30 p.m. Colonel H. Swayne, "The Future of Siberia and her Neighbours."

Alpine Club, 23, Savile-row, W., 8.30 p.m. Major Sir F. de Filippi, "The Italian War Zone."

TUESDAY, DECEMBER 11...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. Sidney Webb, "A New View of International Trade."

University of London, University College, Gower-street, W.C., 5 p.m. Professor S. D. Adshead, "Housing Problems after the War." (Lecture VI.)

WEDNESDAY, DECEMBER 12...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Lord Charnwood, "Technical Training for Disabled Soldiers and Sailors."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. A. E. L. Chorlton, "The Agricultural Power Unit: some Factors governing the Design of a Small Tractor."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. E. J. Pilcher, "The Covenant Ceremony among the Hebrews."

Faraday Society, at the Chemical Society, Burlington House, W., 7.50 p.m. 1. Annual General Meeting. 2. Discussion on the following papers:—(*a*) Dr. J. W. McBain, "Note on the System of Recording Rate of Chemical Reaction"; (*b*) Mr. E. B. Ludlam, "The Effect of Hydrogen Chloride on the Nitrogen-Hydrogen Equilibrium"; (*c*) Dr. E. B. Maxted, "The Influence of Carbon Monoxide on the Velocity of Catalytic Hydrogenation"; (*d*) Mr. A. L. Feild, "The Viscosity of Blast Furnace Slag and its Relation to Iron Metallurgy. A New Method of Measuring Slag Viscosity at High Temperatures"; (*e*) Mr. G. Le Bas, "A Study of the Refractivities of Saturated and Unsaturated Compounds" (Parts I. and II.); (*f*) Dr. A. W. Porter, "The Thermal Properties of Sulphuric Acid and Oleum"; (*g*) Mr. W. R. Bousfield, "On Iso-piestic Solutions."

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m. Hon. F. M. B. Fisher, "Imperial Trade."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Mr. H. J. Gauvain, "Some Aspects of the Tuberculosis Problem: Treatment and Training of Surgical Tuberculosis Cases."

British Academy, at the Chemical Society, Burlington House, Piccadilly, W., 5 p.m. Professor C. H. Firth, "The Dispersion and Destruction of Historical Records during the War."

THURSDAY, DECEMBER 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. D. T. Chadwick, "The Trade of India with Russia, France, and Italy."

Royal Society, Burlington House, W., 4.30 p.m.

British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. (Schweich Lectures.) Rev. Professor C. F. Burney, "Israel's Settlement in Canaan: the Biblical Tradition and its Historical Background." (Lecture I.)

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. A. W. Hill, "Seeds with a Stony Endocarp and their Germination." 2. Mrs. R. Haig Thomas, "*Inter se* Experiments in Pheasant Crossing in evidence of Mendel's Law."

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. J. R. H. Weaver, "Architectural Photography."

Optical Society, at the Imperial College of Science South Kensington, S.W., 8 p.m. 1. Mr. J. W. French, "Proposed Standard Optical Notation and Sign Convention." 2. Mr. T. Smith, "Optical Nomenclature and Symbolism."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 5.30 p.m. Messrs. L. B. Atkinson and A. J. Stubbs, "The Metric System."

Historical Society, 22, Russell-square, W.C., 5 p.m. 1. Madame I. Lubimenko, "The Correspondence of the Stuarts with the Romanovs in the first half of the Seventeenth Century." 2. Dr. J. F. Palmer, "Henry of Bray's Plague Recipe."

FRIDAY, DECEMBER 14...Astronomical Society, Burlington House, W., 5 p.m.

Engineers, Junior Institution of, 39, Victoria-street, S.W., 7.30 p.m. Mr. J. G. Moon, "Maintenance of Engineering Plant."

Mechanical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Messrs. A. A. Griffith and G. I. Taylor, "The Use of Soap Films in Solving Torsion Problems."

SATURDAY, DECEMBER 15...Automobile Engineers, Institution of (Scottish Section), Technical College, George-street, Glasgow. Professor A. Mellanby, "The Engineer of the Future."

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—December 7, 1917.

No. 3395. DECEMBER 14, 1917. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society of Arts

CANTOR LECTURES.

A full list of the Cantor Lectures which have been reprinted from the **Journal** and published separately may be obtained on application to

THE SECRETARY, John Street, Adelphi, London, W.C.

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. Riall Sankey, R.E., M.Inst.C.E. (1912.) Price 1*s*.

Aeronautics. Three Lectures. By Prof. J. E. Petavel, D.Sc., F.R.S. (1913.) Price 1*s*.

Surface Combustion. Three Lectures. By Prof. William Arthur Bone, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s*.

Motor Fuel. Three Lectures. By Prof. Vivian B. Lewes, F.I.C., F.C.S. (1915.) Price 1*s*.

Coal and its Economic Utilisation. Three Lectures. By Prof. John S. S. Brame. (1917.) Price 1*s*.

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. William George Fearnsides, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s*.

Journal of the Royal Society of Arts.

No. 3,395. VOL. LXVI.

FRIDAY, DECEMBER 14, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, DECEMBER 17th, at 4.30 p.m. (Cantor Lecture.) H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, "Progress in the Metallurgy of Copper." (Lecture III.)

WEDNESDAY, DECEMBER 19th, at 4.30 p.m. (Ordinary Meeting.) PROFESSOR J. WEMYSS ANDERSON, M.Inst.C.E., M.I.Mech.E., Dean of the Faculty of Engineering and Lecturer in Refrigeration, University of Liverpool, "Science and the Cold Storage Industry." The HON. SIR THOMAS MACKENZIE, K.C.M.G., High Commissioner for New Zealand, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

COUNCIL.

At the last meeting of the Council on Monday, the 10th inst., Sir Henry Trueman Wood was elected a member of the Couucil.

INDIAN SECTION COMMITTEE.

A meeting of the Committee of the Indian Section was held on Friday, the 7th inst. Present:—

Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I. (Acting Chairman of the Committee), in the chair; Alan A. Campbell Swinton, F.R.S. (Chairman of the Council), Sir Arundel T. Arundel, K.C.S.I., Thomas Jewell Bennett, C.I.E., Sir M. M. Bhownaggree, K.C.I.E., Sir Valentine Chirol, Sir Frederic W. R. Fryer, K.C.S.I., Sir Henry Ledgard, Colonel Sir Arthur Henry McMahon, G.C.M.G., G.C.V.O., K.C.I.E., C.S.I., Sir Prabashankar Dalpatram Pattani, K.C.I.E., Sir Frederick Alexander Robertson, LL.D., John Augustus Voelcker, M.A., Ph.D., Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with G. K. Menzies, M.A. (Secretary of the Society), and S. Digby, C.I.E. (Secretary of the Section).

CANTOR LECTURE.

On Monday afternoon, December 10th, Mr. H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, delivered the second lecture of his course on "Progress in the Metallurgy of Copper."

The lectures will be published in the *Journal* during the Christmas recess.

JUVENILE LECTURES.

A course of two lectures, adapted to a juvenile audience, will be delivered on Wednesday afternoons, January 2nd and 9th, 1918, at 3 p.m., by Mr. P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, on "Animal Camouflage."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

PROCEEDINGS OF THE SOCIETY.

FOURTH ORDINARY MEETING.

WEDNESDAY, DECEMBER 12th, 1917; SURGEON-GENERAL SIR ALFRED KEOGH, G.C.B., M.D., F.R.C.P., Director-General of Medical Services, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barnett, Samuel, London.

Bewsher, Joseph Ponsonby Horatio, Croydon, Surrey.

Bradley, Major Benjamin, Harpenden.
Carter, Wilfrid George, Kingston-on-Thames.
Connal, Allan Ramsay, A.M.I.E.E., East Sheen.
Copley, J. W., Caterham.
Crewdson, Alfred, Alderley Edge.
Foley, Gerald Henry, R.F.C., London.
Gourlay, C. G., London.
Haslam, William Gilbert, J.P., Derby.
Haynes, Ernest, London.
Lyddon, George Edward, A.M.I.Mech.E., London.
Matthey, George Cowper Hugh, London.
Murphy, William Bernard, Peterborough.
Rawlinson, H. W., London.
Smith, Henry White, Bristol.
Smith, John Sugden, Bradford.
Stewart, Samuel, London.
Thornton, John Edward, London.
Walsh, Frank Ford Peregrine, F.R.G.S., London.

The following candidates were balloted for and duly elected Fellows of the Society :—

Birnie, Cyril Montague, Japan.
Boyd, John St. Clair (jun.), Belfast.
Campbell, James, Saltburn-by-the-Sea.
Hirst, Stuart A., Leeds.
Humphrey, George Harold, London.
Kaye, Harry, M.Inst.Met., London.
Pitman, Archibald R. C., W.S., Edinburgh.
Roe, Humphrey Verdon, Manchester.
Voight, Howard Edward Latimer, Stanmore, Middlesex.
Warner, Frank Cloudsley ff., London.
Wiblin, Frederick Avent, Plymouth.

The paper read was—

TECHNICAL TRAINING FOR DISABLED SOLDIERS AND SAILORS.

By Lord Charnwood.

I accepted eagerly the invitation to address you, because, though my knowledge is neither so complete nor so practical as to make my paper strictly worthy of this Society, there are certain simple outlines of my subject which I would like to impress on as many Englishmen of influence in diverse spheres as I can.

My subject is the training of disabled men when necessary. I need hardly refer to their pensions. I shall refer to their curative treatment only so far as that is necessarily associated with their training.

I do not need to tell you, or any British audience, what a debt we owe to our disabled sailors and soldiers, nor that this debt cannot be liquidated in money, but includes the wise and active doing of all that we can to help those among them (the vast majority) whose disablement is only partial to their due place in civil life, so that after the war the average maimed man shall be not less of a man, but, as he well may be, more. You are well aware of the tragic aspect of the problem, and I shall at least make you sensible of its difficulty: let me, before I plunge into long and dry explanations, simply ask you to remember the element of high hope which it involves. I would have you regard it as the first stage in that work of reconstruction after the war which indeed gives many causes of anxiety, but which ought not to be approached without a sense of its vast possibilities of good. Far be it from me to make little of the individual suffering and social harm which will arise if any large number of the cripples and invalids of the war go without the help which is their due; yet I had rather turn your chief attention to this, that among this mass of damaged men there are cases, exceptional no doubt but very numerous, of latent capacity and character, and an unprecedented opportunity now arises of discovering, developing, and directing this capacity and character to the great enrichment of the life of the community.

First, I will try to give you some idea of the size of the problem. We have no right to regard it as unmanageable from its mere magnitude. Up to the end of September 1917 the total number of officers and men discharged from the Navy and Army as unfit for further service was about 225,000—less, I think, than most of us imagined, for we hardly realise how many of the inmates of military hospitals recover completely—and here is a table showing roughly how any average thousand of these disabled men are distributed in respect of the kind of disability from which they suffer :—

Number of Cases in every 1,000 Disabled Men (excluding Officers) so far discharged from Army or Navy during the War.

Cause of Disablement.

Injury to eyes (including an occasional case of total blindness)	32
Amputation of leg	30
Amputation of arm	19
Injury to leg not requiring amputation . .	121
Injury to arm not requiring amputation . .	82
Injury to hand not requiring amputation of whole hand	61
Injury to head (including, say, six or seven paraplegic cases)	47
Hernia	7
Miscellaneous wounds and injuries (including, say, about five paraplegic cases)	54
Total wounds and injuries . . .	453

Diseases of chest (including, say, 60 tubercular cases)	124
Rheumatism	50
Diseases of heart	110
Epilepsy	11
Nervous cases	47
Insanity	9
Deafness (partial, or, in comparatively rare cases, total)	26
Frostbite (including cases of amputation, which are less than one-tenth of the whole)	10
Miscellaneous diseases (among which may be noted, besides a few paraplegic cases, Bright's disease, ulcer of stomach, debility, and varicose veins)	160
Total cases of disease	547
Total wounds and injuries	453
	1,000

I must point out that the proportion of cases of amputated limbs will, at the end of the war, stand somewhat higher, because such cases remain in hospital longer and are discharged from the Services later, and also that a class such as "miscellaneous wounds" or "miscellaneous injuries" includes a certain number of very sad cases indeed. Yet I think we may draw at once two conclusions from this table—the one by way of encouragement, the other by way of warning. The number of palpably grievous injuries is, and, however long the war lasts, will be, well within the compass of the community to deal with as they should be dealt with. On the other hand, there is in our midst a constantly growing number of men more or less enfeebled by injuries of very various kinds and uncertain extent, some of whom will certainly get better, some of whom will get unexpectedly worse. Every neighbourhood in this country, acting with the guidance which central authority can give, has now to grope its way through a problem such as no community has set before itself in any former war—that of finding out how many and which of these men need special help, and how that help can be given. Before leaving this table I must make one further remark in relation to our particular subject to-day. A grievously injured man, say one who has lost his leg, is grievously injured, but it by no means follows that he is specially disabled for his own special trade and needs to be re-educated for another. A tailor or a novelist, who has lost both legs, is a subject for sympathy but not for re-education; on the other hand, a man with a pulmonary trouble, which would impede you or me very little, may have undergone this disaster that his accustomed way of life is precisely that which will make his disorder serious.

Next, you may wish to be briefly reminded of the administrative system, which has now taken its final form for dealing with the disabled. Up to a certain point the naval or military authorities are responsible for the care of these men in their own hospitals. The primary function of these hospitals is, of course, to return men healed and well to the Services. For those who cannot be thus restored, these authorities undertake the responsibility of caring for them in naval or military hospitals just so long as the treatment which those hospitals can supply is on the whole good for the man himself. When that point is passed the man becomes the charge of the Local War Pensions Committee of the county or county borough to which he goes home as a civilian. That Committee is responsible in the first place for his receiving the pension due to him; it is also charged with the payments due to the widows and fatherless, and this business of pensions constitutes, of course, the bulk of its work. It is, however, responsible, in the second place, for making available to him—as a patient to an ordinary doctor, an outpatient in a hospital or special clinic, or an inmate of one of the special institutions for special cases which are being created no faster than they are needed, and yet with very admirable speed—the further medical care which he may require. It is responsible, thirdly, for discovering the need which he may be under of new technical or professional training, and discovering how to supply that need. For this last purpose neighbouring Local Committees can associate themselves together so as to organise technical training for whole large districts of the country. The Local Committees are constituted somewhat differently according to the character of their neighbourhood, but in general include the representatives of every class and every interest concerned. They do their work with the help of sub-committees in different parts of their localities. This local organisation is controlled, guided, and I think we may fairly say inspired, by the Ministry of Pensions, which has now absorbed the powers and duties of the older Statutory Committee; and this Ministry stands in relations of intimate correspondence, in regard to different aspects of its task, with the Admiralty and War Office, who control the hospitals; the Red Cross, who are the pioneers in creating new institutions; the Ministry of Labour; the Ministry of Munitions, which is the employer directly and

indirectly of so much labour; the Board of Education; the Board of Agriculture, and other central authorities. It has a huge task and a new task. It has taken new premises; they are already too small. As a consequence its staff, though large, is also too small; and, as a further consequence, it can claim a little indulgence if its response to an inquiry is sometimes slow. On the whole, we may rest satisfied that our organisation, as an organisation, leaves little to be desired, nor, so far as central authorities are concerned, need we trouble ourselves as to any lack either of capacity or of sympathy on the part of the Ministers concerned or of their staffs.

Now observe the policy adopted in regard to training. If a discharged man desires to be trained for a new occupation, if it appears that he can wisely enter that occupation, and if, through the agency of any technical institution previously existing or created for this purpose, or through that of any private employer, adequate training can be provided for him, Government will pay any necessary fees. It will pay the man during training from 27*s.* 6*d.* a week upwards according to his former Navy or Army rank; it will pay, if he has to leave home, separation allowance which, for example, would bring the income of a man with a wife and three children up to a minimum of £2 13*s.* 9*d.*; it will continue these payments so long as the necessary training lasts; and at the end it will pay the man a lump sum of 5*s.* for every week of training that he has gone through. And there is no limit to the time for which these payments may be continued except the period which expert opinion fixes as sufficient for teaching the trade concerned. This is a large and liberal undertaking. It might be expected to be a slow and difficult task to supply the training required. So it is; but, speaking of the great mass of working-men discharged from the Army who first engage our attention, the real discouragement lies in the fact that very few wish to be trained. If you visit certain great institutions of training you will see a wonderful work going on; but if you call on the Pension Committees of two or three great industrial counties and inquire as to the progress of training, they are pretty certain to say that they have come across very few men who want training or will even accept it when the advantage in their particular case is pressed upon them.

This is no peculiarity of our own country or our own people. Save in the peculiar case of the Belgian disabled, who, having neither trade nor home nor country to go to, are necessarily inmates of one vast institution, it is the same so far as we know in all the belligerent countries. And, I think, the dream of avoiding this foreseen difficulty by some exercise of Army discipline, extended over the soldier long after he had ceased to be a soldier, and fitting him willy-nilly into the new niche in civil life that might be thought best for him, was never anything but a dream. The disabled man may be a complete and permanent wreck, who needs must go to the place of refuge provided; or he may be blind and little inducement is required to take him to that wonderful place of education which the devotion and organising genius of another blind man has built up for him; or he may be, say, a professional pianist with both hands amputated or crippled, who must obviously seek any other form of skill that can be imparted to him. But the vast majority are under no such overwhelming disability; they want to be back at their old home, near their relations and their wife's relations, to sing in the choir of the old church or chapel, to drink in the snug of the old public-house, to be employed about the old works, or to take such advantage as they still can of the high wages now going in the old town. And this they can do. For the very much broken man the old employer can find a light job quite easily; he has lost his right arm, for example, but the employer has a lift which he can work with his left arm. If light jobs in the old shop do not suffice, the demand for men is, as we know, huge, and the demand for half men (even for half-intelligent, uncrippled men, much more for intelligent half-crippled men) is great. What is therefore happening is natural, it is even healthy, nor is it from our point of view this afternoon altogether a misfortune. There is yet a breathing space during which those on whom the responsibility lies, feeling their way as quickly as they can by constantly increasing experience and example, can perfect the means of meeting the need which will come. But the need will come. To a great extent our disabled men, induced by money wages which four years ago would have seemed very high, are remaining unskilled if they were unskilled before, or are even educating themselves down from the skilled to the unskilled ranks. The war will end—eventually, and sooner or later after it the contraction of industry will come; the employer's requirements will alter, his embarrassments will spring up, his business will change hands, or he will fail; some millions of

undisabled and unpensioned soldiers will be then wanting work.

The heavy weight of depression in industry will fall, as always, most heavily on those unskilled ranks in which so many of our soldiers (less frequently our sailors) will have enrolled themselves. That is the great impending evil. But there is, I believe, another already making itself felt. A recovering patient often underrates his recovery; more often, after a while, he over-rates it very much. I give you the impression of at least one able Local Committee, that a large proportion of the men under their charge are going back in health, because they are doing work that is too heavy for them. All this gives us a threatening prospect. By the way, it has its cheerful side. It reflects the average perversity of the working-man, who, on the average, is quite as perverse as other kinds of man; but it does not reflect any prevailing lack of healthy social instincts or of manly energy.

I pass to a brief sketch of the chief schemes now in operation, or well advanced in preparation, for supplying this great need. If what is being done should seem inadequate (fully adequate it can hardly be), I will ask you to remember that in every department of life the country is short-handed, and that those of us who are available for new work are *primâ facie* incompetent for any. I prefer to give you a dull catalogue, which includes a fair number of examples, rather than repeat the fascinating details of any one of these beneficent enterprises. I greatly regret that my friend Major Mitchell, the Director of Training under the Ministry of Pensions, is not in my place at this moment to give account of himself.

I have no concern here with those broken men, never to be forgotten, whose sojourn in institutions such as the Star and Garter (which once enjoyed so different a notoriety) is but the preliminary to a longer rest. Nor ought I properly to refer to those surprising forms of apparently feminine fancy work which afford solace in many hospitals to strong men on their backs; for these belong to recreation, which is an adjunct of cure, and not at all to training; but I would like to advertise that the organising of this form of hospital comfort is a very true work of charity.

I start with an institution, which must be mentioned first because it has led the way in work for the disabled. I mean the Lord Roberts' Memorial Workshops. The fact that these workshops aim at employing the men whom they train, indicates sufficiently the limitation upon their scope. But at the same time it enables them to deal in the best way with cases for which no other agency can so adequately provide; for they are able to set up machinery specially devised for use by disabled men, and in this way to make industrially efficient some who could never have been so under any ordinary employer.

I take next the *blind*. These stand rather apart from the other disabled, because they will so manifestly need a certain supervision and occasional help all their lives. But they are relatively few, and, as you know, the art of helping them has grown to great perfection, and generally their power of recuperation—after a period of dark anguish—is amazing. It is not surprising to learn that there is a considerable field of work for blind men as masseurs, but it marks the length to which skilled instruction can go that an appreciable number of the men at St. Dunstan's in Regent's Park are successfully trained for poultry farming.

Contrast the *deaf*, whom I mention, because, while a blind man attracts sympathy, a deaf, or at least a partially deaf man, is apt merely to irritate us—I will say, if you prefer it, to irritate me. They lie on the fringe of my subject, for the cases of total deafness resulting from the war are so few, and the openings appropriate to them so miscellaneous, that they are hardly subjects for any large general scheme, and should easily be dealt with locally. But partial deafness caused or aggravated by the war is common. It is not a special disqualification for any trade, but it is an impediment in all, except perhaps that of political debate. What I want here to advertise is: first, that partial deafness can very often be greatly alleviated, and that local clinics are now being started for this purpose; secondly, that employers in factories are sometimes afraid of the extra risk of accident to which the deaf are exposed, that the risk is, I believe, exaggerated, and that the partially deaf man can more than counterbalance it by becoming a teetotaller; thirdly, in regard to the quite deaf, that kind people who are likely to meet them can learn, say in an hour, the finger language—I hope I may find that hour and use it myself.

To come now to what I may call the central part of my subject, *cases where a limb has been lost*. Observe that the loss of an arm is generally a far worse handicap than the loss of a leg—happily it is a good deal less common. The degree to which a man can make good such a

grievous loss no doubt varies a good deal with his manhood and general capacity. There is a Berkshire farm labourer at Roehampton who has lost his right arm below the elbow; he is now instructor in poultry keeping and other matters there, and you will not easily find a more efficient farm hand—he is not very young either. In the physics laboratory at Eton one may meet a former gunsmith, who also has lost his right hand; he has charge of and does ordinary repairs to the delicate electrical and other apparatus there, and with his hook and his left hand he can tie knots in a fine silk thread. I have a nephew who, before the war, played conjuring tricks: he had two arms then; he has lost his right arm too completely for any artificial appliance to be fitted on. He still plays conjuring tricks, which personally I could not do with four hands (he has, I should add, a more useful occupation for most of his time, in fact he is now again at the front). Now I do not suppose that the moral courage which such men show is altogether lacking in many of their fellows. I hazard a guess that the loss of a limb would have been to most of us at, say, thirty, a challenge which we should have been inclined to take up. Depend upon it there are limbless men who will do far more than make up for their handicap. But remember that they have first to recover from a tremendous physical shock—not at all as if fairies had gently removed a limb from them in the night. Therefore, if you should be led to visit, say, the Pavilion Hospital at Brighton, where men remain convalescent after operations while their stumps get ready for artificial appliances, or the now famous hospital at Roehampton, which is the first of those centres where they are fitted with such appliances and begin to learn to use them, it would not be wise to approach them with the demand that every man should be practising some new trade or his old trade. Nevertheless, as you probably all know, a surprising number of them, at these and similar institutions, are not only learning new trades as joiners, engineers, electricians, or commercial clerks, but have gone very far indeed in the process. The Exhibition generously organised last summer by Messrs. Sotheby, Wilkinson and Hodge, and to be repeated on a larger scale next year, contained examples of their work which any man would beforehand have called incredible.

Hardly less startling is the work in orthopædic hospitals, such as that at Shepherd's Bush. "Orthopædic" means training a child straight, and has etymologically nothing to do with "pedal" or "pedometer," and Sir Robert Jones and the like of him, including sixty American surgeons who, characteristically, formed the advanced guard of their European army, are occupied in restoring the right use of limbs and joints crippled for the time by any cause, such as the severance of an important nerve. So efficiently do they do this that at least ten in fourteen of their patients go back in some capacity to the Army, and about one in six of the total patients as "A" men. Thus all that they do in these hospitals must be looked at primarily as treatment, not training, and it is supremely important that it should be so looked at. Men making cigarettes there, under tuition supplied by Messrs. Abdulla & Co., are not doing so with any view to a desirable trade opening, but because this occupation, which enlists their interest and their will, is the best thing to restore the lost flexibility of their fingers. For just the same reason other men are swabbing the dirty windows or the like, while a large number of workers in wood, in metal, and in leather—most of them, but not all, belonging previously to these trades—are making the splints and other appliances required by their own and other hospitals. By the way, I would like you to observe that in military hospitals and military convalescent camps neither play nor work of this description is done under any sort of compulsion. It is curative, yet the training is a fact, and the result is that the four in fourteen or thereabouts who will be invalided out of the Army or the Navy go out with their capacity for their old employment largely restored, perhaps enhanced, and a certain number go out having acquired a new trade. Now I will ask you to remember that a good many men are discharged from these hospitals and from others who would benefit greatly by a continuance of orthopædic treatment as out-patients, or who in some cases relapse and would do well to return to such hospitals. Notice, therefore, in the neighbourhoods where you have influence, the progress in the creation of new centres for this largely novel orthopædic treatment, a progress limited, I ought to say, by the comparative fewness of practitioners trained in this particular skill. Watch, if you will be so good, the efforts in your own districts to create orthopædic annexes to general hospitals for the benefit of discharged men, and the development, now projected and destined, I hope, to steady progress, of industrial classes in the technical schools of the same towns, which, working as they will in conjunction with the curative pro-

cesses of the hospitals, are likely to be important agencies in the re-education which we are considering.

In the special institutions for nerve patients discharged from the Army, and in a rather surprising number of cases from the Navy, we learn, as we might expect, that occupation plays at least as large a part in cure as in orthopædic hospitals. It must be a light and attractive occupation, but, apart from that, its character probably makes little difference to its curative value; and for this reason, and since these are men who have done with the Service, the patient's future bread-winning needs can be freely considered. One most interesting experiment in re-education is the training given to nerve patients at Golder's Green in the intensive culture of vegetables under frames and glass bells. Similarly, the chief institutions formed for epileptics are farm colonies.

I must point out that what I have said of Roehampton applies also to the other centres for cases of amputated limbs, of which Erskine Hospital near Glasgow is, perhaps, the best known, and what I have said of Shepherd's Bush applies also to other orthopædic hospitals. I think I have now said all that is necessary of the part that is, or can be, played by hospitals or similar institutions in imparting technical instruction or laying the foundations for it. In so doing I have passed in review the chief of those special disabilities to which a marked and obvious need for new industrial training generally attaches.

But the training given, for example, at Roehampton is, of course, in most cases only a beginning; it has to be carried further in technical schools or in factories or workshops where the employer is willing, as very many employers are, to organise instruction. And besides, there is that large number of miscellaneous invalids of war, of whom I have spoken, and whose varied needs have to be discovered and supplied. You will understand that I cannot give you any complete list of the classes that have been approved by the Ministry of Pensions and are now being carried on in technical schools in many parts of the country; much less can I tell you of the number of instances in which an individual disabled man is learning under an individual employer. I give some examples which show that good work is being done, and which suggest that similar work can be done also elsewhere.

The London Polytechnic in Regent Street has from the first been working in close association with Roehampton, from which most of the 138 disabled men, who are at this moment being trained in it, have come. The courses provided for them include fitting, metal-turning, electrical work, architectural drawing, commercial subjects, tailoring, cinema operating. Their instructors can point to 270 old pupils, all seriously disabled and all now earning good wages.

The Borough Polytechnic has classes in dental mechanics and in baking.

The Battersea Polytechnic has seventy-five men training to be motor mechanics, chemists, electrical workers, or (in the case of a few picked men) sanitary inspectors.

The Northampton Institute in Clerkenwell is training twenty men at telephonic switch-board work.

The Cordwainers' Institute in Bethnal Green Road trains seventy-nine men in boot and shoe making and general leather work.

The course for boot and shoe makers, I should mention, is very thorough; it lasts forty-six weeks. There are, however, repairers who are trained only for six months.

Clark's College in Chancery Lane teaches commercial subjects to seventy-nine disabled men.

Before I pass from London institutions, I wish to pay my tribute to the Eccentric Club, a body, I believe, of gentlemen belonging to the stage. They have illustrated their name by an original and most beneficent work, the foundation of several hostels to afford fitting board and lodging and social advantages to disabled pupils of several London institutions whose own homes are far off. Outside London it would be invidious, and in some cases unjust, to mention the chief towns whose technical schools are or are not being used in like manner. But you must not suppose that the only bright examples are in London, and I think I may mention the Joseph and Jane Cowen Training School at Benwell Grange, Newcastle, a residential college for the training of disabled men in various trades—a pioneer institution of its kind.

Among the notable services by employers stand the training given by Messrs. R. H. Davis and Co., in fancy leather work to a number of disabled men, most of whom remain in their employment, while some of the most proficient go to be instructors to classes that are being set up elsewhere; and the interesting enterprise of Mr. Bernard Oppenheimer. This latter is an endeavour to transfer the diamond-cutting industry to a portion (namely Brighton)

of that British Empire within which most of the raw material is found. Provision is made by Mr. Oppenheimer for the training of 1,500 men.

The Aircraft Federation, I learn, have now formulated schemes which should provide training and employment for at least 5,000 men.

The Munitions Department is active in this matter. Nearly all the (not very numerous) disabled men from one large and very soldierly county that I know, are trained in this department's classes at the Loughborough Technical School.

The Scottish Board of Agriculture is devising, in concert with large landowners, training and employment in forestry.

The English Board of Agriculture has got to work, I do not say too soon, not only on training in forestry, but on training also in horticulture, and in the working of motor tractors. For the pupils in this last occupation, employment can, I understand, be officially guaranteed.

So, you see, the movement does go on, and you must recall that no similar movement has ever gone on in the world before, and looking both to the difficulties of organisation and to the slowness of demand on the part of the men themselves, you will not wonder that the largest of the schemes which I have mentioned are of recent origin. Meanwhile, the further progress of the work is being prepared for by a careful reconnaissance. Committees of employers and employed in a number of the chief branches of industry have been set up by the Ministry of Labour, and have issued, or are preparing general reports on the scope for employment in different trades, and the training that is appropriate. They are producing also a numerous progeny of local sub-committees which will study these matters more in detail, and will overcome, it may be hoped, those difficulties in relation to existing employees which might otherwise cause impediment. The reports already issued may be procured by any one from the Ministry of Pensions.

So far, there is nothing but what is satisfactory to tell about the finding of employment for men that have been trained. But it is not surprising to learn that disabled men have been apt to take a fancy for one or another employment of a kind that is likely to have too many men in it. The occupations of a chauffeur, and of an ordinary not very highly skilled clerk are the chief examples, and these and several others have been black-listed as *primâ facie* unsuitable trades to which to train a man.

I am afraid it does not surprise me to find that the movement for establishing small-holdings for soldiers, invalided or otherwise, of which we once heard much, goes slowly. I hope, not that it will continue to be slow, but that it will continue to be cautious. Agriculture is not the least skilled of occupations, as some seem to think, but the most skilled. Small-holding requires the right soil, the right neighbourhood, the right small-holder. It requires also some capital. Above all, it is a way of life in which a man stakes much on the continuance of his own full strength till he has strong sons to help him. These things are not said by way of crabbing, but of warning, and the warning is meant to apply to the particular idea of small-holdings, not to the wider and most sound persuasion that there is immense scope for the training and employment of skill in relation to agriculture.

You will, I should like to think, ask, What about professional as opposed to mechanical training? Is there not, for example, such an occupation as that of the schoolmaster, in which men will be increasingly needed, in which character and knowledge of human beings count for more than technical method, and in which the man who has fought for his country is, other things being nearly equal, the better man? What is being done in this direction? I hope you will continue to ask these questions loudly and publicly, not with a view to awakening Mr. Fisher, who is awake, but with a view to supporting him. I hope, too, that you will want to know about our disabled officers. Nothing can surpass in its way the beauty of the surroundings in which some of them lie, except the boredom that broods over them. The openings that can be imagined for a good many officers knocked out of their previous work, are very many, and so are the studies, especially in certain modern languages, which would be very useful to many of them, and useless to hardly any. Moreover, the difficulty of combining the purpose of teaching with the primary purpose of a hospital, is not, I submit, so great as it is in the case of a private soldier, whom it would be cruel, as well as mischievous, to set thinking of a new civil job, when his first business is to get well and fight again.

But—for it is high time now that I concluded with some sort of a moral—in this and in all other matters of which I have spoken, it is not the Government, but the public and ourselves that we need to stir. If knowledge and interest on this whole subject be diffused, voluntary initiative in many quarters will set more things

going than in our general survey we can foresee. Upon the whole, we cannot hesitate to say that in this great field Government serves us well.

Returning then to the larger aspects of the subject, I have chiefly this to say: First, it is still more among the men themselves than in what are called influential circles that knowledge and interest need to be aroused. Let them understand more generally both the dangers and the opportunities before them, and if greater opportunities be needed let the demand arise chiefly among them. There is progress in this matter already. I am told that the false idea once prevalent here and in France, that a man would lose in his pension by becoming skilled, is disappearing, and besides, many men who have eagerly taken up well-paid blind-alley work, or work for which they were physically unfit, must be beginning to reflect about it. Everyone who visits hospitals, and everyone connected with large works, should interest himself or herself in this. There need be no intrusion, no offering of advice which offered to ourselves would seem impertinent. General talk on what is being done, and what needs to be done, will set the man himself inquiring. Above all, it is working-men and working-men's leaders who can talk straightest and most shrewdly—as Mr. Gosling, for example, has talked—to the soldier who must go back to the workshop. Secondly, next to the men themselves, an appeal must be made not to important quarters in London, but to the local public opinion which influences local authorities and stimulates local leaders. Generally speaking, local administration is as sound and sensible in this matter as in most others that relate to the war. But local war pensions committees are burdened with much pressing work as to pensions, and in this matter, may I repeat, all that is being done is of the nature of a new invention, and new inventions need advertising. There are localities, too, where the whole war pensions business is being run on routine lines as one of the many odd jobs which town clerks and their offices have to take on now, when a special officer is really wanted for the work. And there are localities, far more numerous, where between the good employment which prevails for the moment among the discharged, and the difficulty of devising what is wanted in the way of training, the idea of training has naturally enough lapsed. And as for the keen local authorities, I do not suppose there is one which is not hard worked or (except in favoured neighbourhoods) which does not feel the need of volunteer helpers who will take to such work and stick to it.

Well, I know I have not given you all the information you desired, but I am vain enough to hope that perhaps I have stirred in you precisely that blend of dissatisfaction and of hope which this great and pregnant topic demands.

DISCUSSION.

The Chairman (Sir Alfred Keogh), in opening the discussion, said he had been interested in the subject with which the paper dealt ever since the beginning of the war. The author had called attention to the fact that no similar movement had ever taken place in the world before, and that was literally true, although such movements on a smaller scale had often been required before. He could remember many campaigns in which the care of the maimed and those afflicted in other ways than the maiming of their bodies had been entirely neglected; in fact, in this country it had been the rule simply to pay the discharged soldier his pension and let him look after himself. In the case of the present war it was the magnitude of the work to be done in the direction to which the author had alluded that was of importance. That importance would continue to increase and would be very evident to the public when demobilisation took place, although it might not be so obvious at the present moment. In his opinion, with the exception of the war itself, which of course came first, nothing was of greater importance than the diffusion of knowledge upon the subject, and the success of the undertaking depended upon that knowledge being diffused in good time. The author had dealt almost entirely with the training of the soldier, but the question of the treatment of the soldier was of equal importance. The military hospitals were doing as much as they could in the matter of the treatment of the soldier, but when peace was proclaimed men who had been soldiers, and whose engagements in the Army were terminated, would have a right to return to civil life. There would not be—and there ought not to be—any power to retain them in the hospitals; therefore many of those men would come out of the hospitals without being fully cured, and would be handed over to the Government to be cared for after their discharge. It required little imagination to realise that that was going to be a tremendous problem. The author had stated in his paper that the Government was doing successfully all that a Government ought to do in the matter, and he could very warmly echo that opinion. A great deal of all that had been done with regard to the treatment of the serving soldier within the last three years, in the various hospitals and other institutions, could not have been accomplished without the aid of the civil population, who had rendered invaluable volun-

tary service; but he thought the great question of the treatment and training of the discharged soldier should receive an equal amount of attention from the general public. He wished to see committees and voluntary organisations springing up in every town and village in the country for the specific purpose of looking after the discharged soldier, just as similar voluntary organisations had been formed for the benefit of the serving soldier. The former work might not be so romantic as the latter, but he ventured to say it was infinitely more important. The authorities who were responsible for the work were doing all they could to make it a complete success, but he did not think that success could be achieved without the aid of the general public. He hoped the author's words would reach from one end of the country to the other, as they dealt with a subject of tremendous importance, socially and economically. Those wen who were permanently disabled in fighting the battles of their country, were entitled to that country's gratitude.

THE SECRETARY read the following letter from the Right Hon. Sir Frederick Milner, Bt.:—

December 11th, 1917.

DEAR MR. MENZIES,

I had hoped to be able to be present at Lord Charnwood's paper to-morrow, but the time is an awkward one for me, and I fear it will not be possible. My deafness would have prevented my hearing much of what went on.

Had I been present, I should have liked to say that, as far as London went, the technical training for soldiers and sailors is very satisfactory, and the work of the Eccentric Club hostels is most valuable in housing the men who are learning.

I fear things are not so satisfactory in the provinces, and it seems to me that Local Pension Committees have very little knowledge of their duties, and their powers in this direction. In many places nothing at all is being done in this direction. In others, where an attempt has been made to train men, complaint has been made that they get very little assistance or advice from headquarters. One crippled man in the Pontefract district was very anxious to learn boot-making, but he said he had been waiting week after week, and nothing was done.

I have had complaints from men from all over the country, saying they could get no facilities whatever for learning a trade. At York, which is a large military centre, I find that so far only five men have been given the opportunity of learning trades.

I hope it may be possible to take steps to acquaint local authorities of their duties in this direction, and of their powers.

I do not know if it will be possible to read this letter at your meeting, but I think it is a subject worthy of discussion, and I should like to know the views of Lord Charnwood and others about it.

Very sincerely yours,

(Signed) FRED. MILNER.

P.S.—I may mention that our Roberts' Memorial Workshops are a very valuable means of employment for crippled men, and our numbers are daily growing. We are always glad to take in cases that are brought to our notice. We train the men ourselves.

MAJOR ROBERT MITCHELL (Director of Training under the Ministry of Pensions), said that in answer to Sir Frederick Milner's criticism, he thought it only fair to say that there were reasons why in many large industrial centres more had not been done. It was the desire of the Ministry of Pensions that the training in question should be of such a character that the men when trained would not be like black sheep amongst their fellow-workers, but would be welcomed and treated as part of themselves. Special arrangements had therefore to be made, which had taken a long time to develop because there were so many interests to consider. Special Training Advisory Boards, consisting of representatives of the leading Trade Unions and Masters' Associations, had met at the Ministry of Labour and considered all the difficulties with regard to the matter, with the result that there were now eleven declared trades with all the special arrangements made whereby discharged soldiers might receive their training. The conditions under which the men would receive their training, the length of such training, and the rate of wages they would receive, had all been settled, which was a result worth waiting for, because the men would become respectable and independent members of their trade, and if they carried out the conditions laid down for the periods of training the Trade Unions would even accept them as members. The shipbuilding and engineering trade and the aircraft industry had now completed their reports, and the reports of a number of other trades, which would absorb almost as many men as required training, would be issued within the next two or three months. Until the necessary arrangements had been made, it was impossible for Local Committees in the various centres to formulate schemes of training, because there were no regulations under which the training was to be given, and no assurance that the men when trained would be properly treated by the employers. The Ministry of Pensions was doing all it could to deal with those disabled soldiers who needed outdoor employment, such as those suffering from tuberculosis, shell shock, etc. Arrangements were being made, in connection with the Board of Agriculture, to provide training in market gardening, and the authorities at Kew Gardens had offered to train men in horticulture. These employments, however, required a certain amount of energy which many of the disabled men were not able to devote to them, and an appeal might be made to the patriotism of golf clubs to provide light employment for such men. There were serious difficulties with regard to one-armed men, and a great deal of gratitude was due to the Lord Roberts' Workshops

for the help they had given in providing special employment for such men. It was not impossible to train them for many employments, and some were now earning more wages than they did in pre-war days. He felt the great need was to stir up public opinion with regard to the whole subject; the public should know what was being done and what facilities were being offered for the training of discharged soldiers. Advertising of that kind was being carried on at the present time in many parts of the country by means of lectures, illustrated by lantern-slides and cinema films, giving full particulars of all the facilities that were being offered. No one could be more anxious than the Minister of Pensions that everybody should know what was being done, and no effort would be spared to provide all the facilities that discharged soldiers required. The Ministry of Pensions hoped that by the end of February there would not be a single disabled man in this country who would not have ample provision made for his instruction either in technical schools, most of which had come forward and rendered valuable assistance, or in the various workshops where special courses of training, extending over periods of from six months to three years, had been established, and where the men would receive a good living wage.

MAJOR A. TUDOR CRAIG (Incorporated Soldiers and Sailors Help Society) said it was very important to be able to guarantee permanent employment to the men in the trade in which they had been trained. He advocated that all those who were to undergo training should be most carefully selected to see that they were fit for the trade they proposed to enter. If they could carry on the same trade in which they had been occupied before the war it would be much better to let them do so, as they would have a much better chance of obtaining employment. At the present moment many of the men were a little off their balance, and had a very exaggerated idea of their own value. Employers would find that that was the case, and they would have great difficulty in dealing with such men. He had recently received a letter from an employer who had in his factory 867 men disabled in the war, and he wrote quite hopelessly of the future of those men, saying that they were extremely difficult to deal with. In Lord Roberts' Workshops, which he had the honour to control, exactly the same state of affairs prevailed. About 20 per cent. of the men were splendid and could earn good wages; 40 per cent. were men who liked to come and go as they pleased, and would not stick to their work; and the remaining 40 per cent. were really impossible to deal with. With regard to Major Mitchell's reference to one-armed men being largely dealt with at the Lord Roberts' Workshops, there were now nearly two hundred such men employed there, chiefly in connection with machinery. The speaker produced a walking-stick made by a one-armed man from part of the wing of a German aeroplane brought down in this country. He did not think that employers after the war would be prepared to take one-armed men into their employment when they could obtain able-bodied men to do the work, and he thought it was only at such institutions as Lord Roberts' Workshops that one-armed men could be guaranteed permanent employment. He hoped the necessity of guaranteeing the men permanent employment would be kept very strongly in view by all those who were dealing with the matter.

MR. DUDLEY B. MYERS (Queen Mary's Convalescent Auxiliary Hospitals, Roehampton) said that they were rather favourably situated at Roehampton, because the misfortune of men who had lost a limb was such as to attract the sympathy of employers throughout the country, perhaps to a more marked degree than in the case of other forms of disablement. The trouble at Roehampton had not been to find work for the men, but to find men for the work offered. The psychological aspect of the problem was, of course, a difficulty; there were so many men of different classes and temperaments at Roehampton, and the personal equation was always a difficulty. When the hospital was first started, its originators recognised that it would not be sufficient to supply the men with artificial limbs, but that it was necessary to provide them with some form of training for an occupation after they left. Lady Wantage at once came forward and offered to present and equip workshops in connection with the hospital, which were erected under the superintendence and on the designs of Major Mitchell. The hospital at Roehampton had an advantage in the large number of its patients, in that they could be dealt with collectively. There were never less than 550 there at a time, and those men could be not only dealt with individually but collectively. They had the stimulus of the example of others who were working there, and also the example of men who had gone through the training and were earning good money, and who came back to the hospital occasionally for the repair of their artificial limbs. The men at Roehampton were thus surrounded by many inducements of one kind and another, and the effect of these inducements was very marked. The author had mentioned the difficulty of inducing men to undergo training, and he believed that was a true statement of the position. The average man when discharged from the Army did not know what kind of work would suit him, and did not know what kind of training to take up. When a man had a definite disablement, however, such as the loss of a limb, one knew exactly what that man could do and what his limitations and capacities were. There were five different training sections at Roehampton, and the men were allowed to try them all in turn if they liked, until they found the work that suited them. Many of the men at Roehampton had the additional advantage of having first passed through the work-

shops equipped on similar lines at the Pavilion Hospital at Brighton, where they received every encouragement and an excellent training. About nine thousand men had been handled industrially at Roehampton; 40 to 42 per cent. went back to their old employment; 33 to 35 per cent. went back to their homes in different parts of the country, and took up some form of industry there; and about 25 per cent. of the men were prepared to accept work anywhere.

Sir Robert Armstrong-Jones, M.D., F.R.C.S., F.R.C.P., thought the subject of the paper was one of supreme and overwhelming interest. He had had some experience in dealing with mental cases, and he believed if those men could be taken from the towns into the country it would have a very good effect on them. He felt rather disappointed that the author did not look more favourably upon settling disabled soldiers upon the land.

Mr. Warwick Draper thought a point of great importance was the association of training in agricultural pursuits with medical treatment in village centres, especially in the case of men suffering from shell shock, neurasthenia, etc., who might be encouraged to restore the life in our countryside. Such men should not be employed in the hard work demanded by small holdings, but in such pursuits as intensive culture and horticulture, and in the trades ancillary to those. In that way there was a great opportunity to restore the social fabric of a re-created and healthy peasantry and yeomanry in England. The Committee with which he was connected, and of which Dr. Fortescue Fox was the Chairman, were working out a scheme to combine vocational training with medical treatment in the manner he had indicated.

Dr. R. Fortescue Fox expressed his gratitude for the service the author had done in definitely associating medical care with the great problem of re-education.

On the motion of the Chairman, a hearty vote of thanks was passed to Lord Charnwood for his interesting paper.

Lord Charnwood, in reply, said that he did not wish to pour too much cold water on the idea of small-holdings, but he thought there was a certain number of people who favoured that scheme and did not realise the difficulties involved in it.

OBITUARY.

Charles Hawksley, M.Inst.C.E.—Mr. Charles Hawksley died on November 27th, at the age of seventy-eight. He was born in Nottingham in 1839, and after being educated at University College, London, he entered the offices of his father, the late Mr. Thomas Hawksley, F.R.S. In 1866 he became his father's partner, and he continued the business after his father's death in 1893. The firm was mainly engaged in waterworks engineering, gas and sewerage works. Mr. Hawksley was President of the Institution of Civil Engineers in 1901, and was serving at the time of his death on the Council of the Institution of Mechanical Engineers.

Mr. Hawksley was elected a member of the Royal Society of Arts in 1902. His father was also a member from 1868 to the time of his death in 1893, and he served on the Council as a Vice-President of the Society from 1888 to 1892. His son, Mr. Kenneth Phipson Hawksley, is now a Fellow, having been elected in 1902.

GENERAL NOTES.

Faraday Society. — A general discussion on "The Setting of Cements and Plasters" will be held on Monday, January 14th, 1918, at 5.30–7.0 and 8.30–10.30 in the Rooms of the Royal Society of Arts. The following papers will be read: Dr. C. H. Desch (Glasgow), "The Mechanism of the Setting Process in Plaster and Cement"; Professor H. Le Chatelier, "Crystalloids *v.* Colloids in the Theory of Cements"; Mr. A. A. Klein (Worcester, U.S.A.), "The Constitution and Hydration of Portland Cement"; Mr. George A. Rankin, (Creighton, U.S.A.), "The Setting and Hardening of Portland Cement"; Mr. Bertram Blount, "The Setting of Cement in its Relation to Engineering Structures"; Mr. John Rhodin, "Note on the Colloidal Theory of Setting"; Mr. E. H. Lewis and Monsieur E. Deny, "The Effect of the Addition of Suitable Slag on the Setting Properties of Portland Cement"; Mr. W. J. Dibdin, "Ancient and Modern Mortars."

Victoria and Albert Museum.—A commemorative exhibition of the works of the late Auguste Rodin has been arranged at the Victoria and Albert Museum, and is now on view in the East Hall, near the Cromwell Road entrance. In the early months of the war, as will be remembered, Rodin gave to the nation, for preservation in the Museum, a magnificent group of his works, with the express intention of symbolising in the gift his admiration for British soldiers fighting side by side with his own countrymen. This collection, which is probably the largest individual collection of Rodin's works outside Paris, has now been supplemented by a number of other works, which their owners have generously lent to the Museum for this exhibition. Among these may be mentioned a marble group, "Les Benedictions," from the Tower of Labour; busts of Legros, Gustave Geffroy, Lord Howard de Walden, and Mrs. Charles Hunter; "L'homme au nez cassé," and a small version of Le Penseur.

Farthings.—The Chancellor of the Exchequer, replying to a question in the House of Commons on November 29th, stated that 42 tons of farthings, or 15,000,000 pieces, had already been issued in the eleven months of this year, an amount about three times the issue for the whole of 1914.

MEETINGS OF THE SOCIETY.

Ordinary Meeting.

Wednesday afternoon, at 4.30 p.m.:—

December 19.—Professor J. Wemyss Anderson, M.Inst.C.E., M.I.Mech.E., Dean of the Faculty of Engineering and Lecturer in Refrigeration, University of Liverpool, "Science and the Cold Storage Industry." The Hon. Sir Thomas Mackenzie, K.C.M.G., High Commissioner for New Zealand, will preside.

Cantor Lectures.

Monday afternoon, at 4.30 p.m.:—

H. C. H. Carpenter, M.A., Ph.D., M.Inst. M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology. "Progress in the Metallurgy of Copper." Three Lectures.

Syllabus.

Lecture III.—December 17.—Converter practice—Refining and casting—Treatment of tailings—Flue-dust treatment—Extraction and purification of white arsenic—Electrolytic refining at the Raritan works—Production of commercial copper. Pyritic smelting at the Tennessee Copper Co.—Hydro metallurgy—Leaching at Chuquicamata—Present-day methods of extraction of native copper at Calumet—Treatment of mixed sulphide and oxide low-grade ores. Tendency of modern metallurgy.

Position of the industry in Great Britain to-day. Importance of copper refining—Chief commercial varieties of copper, including tough-pitch arsenical copper—Need for exhaustive inquiry into the various aspects of the industry from the standpoint of Empire requirements, and of action to be taken on the basis of the results of the inquiry.

Papers to be read after Christmas:—

Lord Leverhulme, "The Relations between Capital and Labour—Reasonable Hours, Copartnership, and Efficiency." W. A. Appleton, C.B.E., Secretary of the General Federation of Trade Unions, will preside.

Sir William H. Clark, K.C.S.I., C.M.G., Comptroller-General of the Commercial Intelligence Department, "The Organisation of Commercial Intelligence." The Right Hon. Lord Faringdon will preside.

Alexander Newlands, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in the British Isles."

Frank Stuart Courtney, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." Sir John Snell, M.Inst.C.E., will preside.

Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." Sir William A. Tilden, D.Sc., LL.D., F.R.S., will preside.

Maurice B. Adams, F.R.I.B.A., "Picturesque Architecture." Sir Aston Webb, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

Wm. Frecheville, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

Alfred Dickinson, M.Inst.C.E., "Water Power in India."

H. M. Surtees Tuckwell, M.I.Mech.E., "The Tata Iron and Steel Works" (India).

Sir Henry Ledgard, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India."

Hon. Sir Dinshaw E. Wacha, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana."

C. du P. Chiappini, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

The following series of papers has also been arranged, dealing with the Application of Scientific Research to the Development of particular British Industries:—

Reginald S. Clay, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry."

George Martineau, C.B., "Sugar from several Points of View."

John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. Lawrence Ball, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

Sir William George Watson, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." Sir Arthur D. Steel-Maitland, Bt., M.P., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

January 17, February 14, March 14, April 18, May 30.

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

February 5, March 5, April 30.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced) :—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

January 21, 28, February 4. At 8 p.m.

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: The Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

JUVENILE LECTURES.

Wednesday afternoons, at 3 p.m. :—

P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage." Two Lectures.

January 2 and 9.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, DECEMBER 17...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Professor H. C. H. Carpenter, "Progress in the Metallurgy of Copper." (Lecture III.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. A. H. Finn, "The Mosaic Origin of the Pentateuch."

British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. (Schweich Lectures.) Rev. Professor C. F. Burney, "Israel's Settlement in Canaan: the Biblical Tradition and its Historical Background." (Lecture II.)

Engineers, Society of, at the Geological Society, Burlington House, W., 5 p.m. Mr. E. W. C. Kearney, "High Speed Railways."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Second Lieutenant J. M. Wordie, "The Drift of the 'Endurance.'"

Engineers, Junior Institution of, 39, Victoria-street, S.W., 7.30 p.m. Mr. C. R. Turner, "Engineering in the Brewing Industry."

East India Association, Caxton Hall, Westminster, S.W., 4.15 p.m. Sir Charles Armstrong, "Commercial and Industrial Development in India."

TUESDAY, DECEMBER 18...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Address by Mr. A. P. Trotter.

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. H. Cunningham Craig, "The Prospective Oilfields of Barbados."

Statistical Society, at the Surveyors' Institution, Great George-street, S.W., 5.15 p.m. Sir R. H. Rew, "The Prospects of the World's Food Supplies after the War."

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. W. L. L. Brown, "The Buenos Aires Western Railway Tunnels under the City of Buenos Aires."

WEDNESDAY, DECEMBER 19...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Professor J. Wemyss Anderson, "Science and the Cold Storage Industry."

Röntgen Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. P. Bolton, "Computation of Wind Velocity from Pilot Balloon Observations." 2. Mr. E. G. Bilham, "The use of monthly Mean Values in Climatological Analysis."

Geological Society, Burlington House, W., 5.30 p.m.

Microscopical Society, 20, Hanover-square, W., 8 p.m. Professor W. Bateson, "Cytology and Genetics."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Lord D'Abernon, "Public Health and Alcoholism in Women."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m. Mr. W. C. Dawson, "Democratic Ideals in Imperial Reconstruction: some neglected dangers, and suggested safeguards."

THURSDAY, DECEMBER 20...London Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4 p.m. Mr. J. Slater, "Old Marylebone."

Royal Society, Burlington House, W., 4.30 p.m.

British Academy, in the Theatre, Burlington-gardens, W., 5.30 p.m. (Schweich Lectures.) Rev. Professor C. F. Burney, "Israel's Settlement in Canaan: the Tradition and its Historical Background." (Lecture III.)

Chemical Society, Burlington House, W., 8 p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. E. A. Ashcroft, "A Neglected Chemical Reaction and an Available Source of Potash." 2. Mr. J. J. Garrard, "Syphoning Gravel."

Japan Society, 20, Hanover-square, W., 3.30 p.m. Mr. J. Blair, "The Japanese Mercantile Marine."

Concrete Institute, 290, Vauxhall Bridge-road, S.W., 5.30 p.m. Messrs. H. K. Dyson and E. Marsland, "The Effects of Fire on Reinforced Concrete Buildings as demonstrated by some Recent Examples."

Camera Club, John-street, Adelphi, W.C., 8.15 p.m. (Ten Minutes Lecturettes by Member.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—December 14, 1917.

No. 3396. DECEMBER 21, 1917. Vol. LXVI

Journal of the Royal Society of Arts

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

Registered as a Newspaper.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,396. VOL. LXVI.

FRIDAY, DECEMBER 21, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

CANTOR LECTURE.

On Monday afternoon, December 17th, Mr. H. C. H. Carpenter, M.A., Ph.D., M.Inst.M.M., A.R.S.M., Professor of Metallurgy, Imperial College of Science and Technology, delivered the third lecture of his course on "Progress in the Metallurgy of Copper."

On the motion of the Chairman, a vote of thanks was accorded to Professor Carpenter for his interesting course.

The lectures will be published in the *Journal* during the Christmas recess.

INDIAN SECTION.

Thursday afternoon, December 13th; Rt. Hon. Lord Islington, G.C.M.G., D.S.O., Under-Secretary of State for India, and subsequently Sir Charles C. McLeod, in the chair. A paper on "The Trade of India with Russia, France, and Italy," was read by Mr. D. T. Chadwick, I.C.S., Indian Trade Commissioner.

The paper and discussion will be published in the next number of the *Journal*.

JUVENILE LECTURES.

A course of two lectures, adapted to a juvenile audience, will be delivered on Wednesday afternoons, January 2nd and 9th, 1918, at 3 p.m., by Mr. P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, on "Animal Camouflage."

Special tickets are required for these lectures. They can be obtained on application to the Secretary.

A sufficient number of tickets to fill the room will be issued to Fellows in the order in which applications are received, and the issue will then be discontinued. Subject to these conditions, each Fellow is entitled to a ticket admitting two children and one adult. Fellows who desire tickets are requested to apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

FIFTH ORDINARY MEETING.

Wednesday, December 19th, 1917; The Hon. Sir Thomas Mackenzie, K.C.M.G., High Commissioner for New Zealand, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Anderson, Gilbert, London.
Attwater, Richard, Preston.
Baroda State, The Minister of Education, Baroda, India.
Boote, Edgar M., Coventry.
Bradshaw, Granville E., Walton-on-Thames.
Chadwick, David Thomas, I.C.S., Kent.
Coatalen, Louis, Wolverhampton.
Diamant, A. St. John, L.R.I.B.A., Egypt.
Forster, Martin O., D.Sc., Ph.D., F.R.S., London.
Lo Tian Cheok, The Hon., Borneo.
Mastin, John, D.Sc., Litt.D., Kenyon.
Mort, George Frederick, London.
Pegler, Frank, Retford.
Sempill, Squadron Commander, the Master of, R.N.A.S., London.
Ware, Alfred George, Bournemouth.
Willis, Thomas Wilkinson, Sheffield.

The following candidates were balloted for and duly elected Fellows of the Society:—

Berwick, F. W., London.
Delpech, Reginald, London.
Hackett, W. W., Birmingham.
Hall, Robert Swainson, Portuguese Congo.
Lake, Joseph Lenegan, London.
Lambert, Arthur Reginald, Sevenoaks.
Laws, Robert George, London.
Samuel, Henry, London.
Seth, Mesrovb Jacob, Calcutta.
Waring, S. J., London.

THE CHAIRMAN, in opening the meeting, said no one could over-estimate the enormous possibilities associated with the cold storage industry. It had changed the conditions in New Zealand from profitless occupations to prosperity. Before the frozen meat industry was introduced, sheep in New Zealand were not worth more than sixpence or a shilling, and the transformation that had taken place read like a fairy story. Immediately before the introduction of cold storage, there were about 12,000,000 or 13,000,000 sheep in New Zealand, and it was then thought that not more than a quarter of a million could be exported without depleting the flocks and herds, but the export had now reached 6,000,000 annually, and New Zealand had sent to this country 47·5 per cent. of the total mutton and lamb that had been imported, 106,000,000 carcasses having been exported to this country by New Zealand up to the end of 1916. With regard to the dairy industry, before the organisation of that industry in New Zealand, and the application of cold storage, the total exports were £4,000,000, whereas now they were £7,000,000 per annum. If that could be done in a small country like New Zealand, great things might be expected with scientific study and research.

The paper read was—

SCIENCE AND THE COLD STORAGE INDUSTRY.

By J. WEMYSS ANDERSON, M.Eng., M.Inst.C.E., M.I.Mech.E.,

Dean of the Faculty of Engineering, and Lecturer in Refrigeration, University of Liverpool.

The value of perishable produce imported into this country, subject more or less to refrigeration, was, pre-war, about £130,000,000 per annum. The greater amount* of this sum was represented by the values of beef, mutton, pork, rabbits, bacon, ham, butter, cheese, eggs, fruit, lard, margarine, poultry and game. In future returns fish will, no doubt, occupy an important position. In normal peace times a good and cheap food supply is always highly placed in the list of *desiderata* of national prosperity. Under war conditions, food supply is classed under the heading of "National Importance." Further, transport and preservation are always prime factors in food supply, but in an island empire they become factors of the first order.

It is abundantly evident that the most natural means of preserving foodstuffs, viz., by means of low temperatures, has gained the confidence of our merchants, and the cold storage industry to-day is a striking example of the successful combination of science, commerce, and industry. It would be useless to contend that in this combination there are no weak links in the chain that binds the three together—indeed, the object of this paper is to point out one of the weak links and suggest methods for strengthening it.

* See Appendix I.

If "reconstruction" has any meaning at all, it is that in the years immediately following the declaration of peace, there must be no weak links in any industry; all the chains must be uniformly strong and capable of withstanding the combined pull necessary to maintain our commercial supremacy. It had been the intention of the author to give a brief history of the cold storage movement, but he has found it impossible to do justice to the subject in a way suitable to the scope of the paper. The history, however, reveals four outstanding features:—

(1) That its merchants have been typically British—indeed, it is hard to imagine a more striking example than the cold storage industry affords of the success of the spirit of enterprise and love of adventure, which, combined with a stern sense of equity and justice, has always characterised British commerce.

(2) That refrigerating engineers have been in no sense less typical, inasmuch as the methods employed are scientifically sound, the machines of the leading manufacturers are thoroughly reliable, and the necessary low temperatures for the transport and storage of food have been made a sound commercial proposition.

(3) That refrigeration has played a most important part in the development of some of our Colonies—particularly Australia and New Zealand. Refrigeration will still remain of the first importance to these Colonies, and will become a greater factor in Canada, South Africa, India and Egypt. It should be said that Canada has done excellent work in refrigeration, both scientifically and practically; but it would not appear that her development has depended on it to the extent that obtains for Australia and New Zealand.

(4) That while the applied science of the engineer has done much for the advance of cold storage, pure science has in this country done little or nothing for the commercial preservation of foodstuffs.

This is the weak link previously referred to. This link can be strengthened, indeed, it must be strengthened if this country is to prevail.

The principal foodstuffs at present cold stored (see Appendix I.) can be roughly divided into three classes:—

(1) Produce whose life history is finished, such as all classes of meats, poultry, rabbits and fish.

(2) Produce whose life history is not finished, such as fruit and eggs.

(3) Milk and produce from milk—cream, butter, and cheese.

The mention of "life history" is sufficient to show the peculiar blend of knowledge required to deal with proper understanding with the materials mentioned. It is astonishing to what heights the merchant and engineer have already soared; but, however keen the scientific penetration of those practically engaged in the cold storage industry to-day, there can be no doubt that pure scientific, medical, and veterinary knowledge and research must be brought to bear on the subject.

What are the types of problems awaiting solution? Taking examples from the three sections in order, there is first the problem of chilled beef.

It has been found that with good rearing of sound stock, combined with scientific methods of slaughter, and a thorough system of veterinary inspection and hygienic after-care, beef can be kept in the chilled (soft or unfrozen) state for five or six weeks. This time permits of a voyage from North or South America, together with the time necessary for collecting the cargo at one end and its distribution at the other—in this country. This present time allowance cuts out all possibilities of a chilled beef trade with Australia or New Zealand with low temperatures only.

Methods have been propounded and even carried out. Are these methods sound from a dietetic standpoint? Can science aid our Colonies with a definite pronouncement on the subject? It remains to be said that chilled beef is financially sounder than frozen beef.

Then again, with all classes of meats, poultry, and rabbits, certain troubles manifest themselves from time to time—such as mould. Often the troubles are epidemic and caused by ignorance or carelessness prior to shipping, while often only a small percentage of an overseas consignment is affected and the source of trouble cannot be found by the trader. The loss—whoever bears it financially—is not only a loss of wealth, but a loss of food to the nation.

Then again there is the problem of fish. Fish has been preserved in many ways, but it is safe to say that refrigeration is destined to outrival, in bulk, all other methods. Research work is urgently needed in this direction, both with respect to meeting periods of glut * and for general preservation and transport. Such work should not be confined to narrow limits; a very broad view must be taken and all methods reviewed, the main questions to be determined being:—

(1) What kinds of fish will stand preservation the best?

(2) What are good methods, and, if possible, the best with each kind of fish?

(3) The seasons of the year best adapted for each form of preservation.

(4) The food values and general effect for each method of preservation on the principal kinds of fish.

In refrigeration alone, no one method will hold good for all kinds of fish—some will not stand freezing at all, some will stand it well for a short period, others for long periods. Some will require quick or sharp freezing, others will stand a slower method. Most fish will require gutting before treatment, others will probably keep sufficiently long in a frozen state ungutted.

When the best methods have been determined, there still remains the problem of educating the public taste. It will be useless to preserve thousands of tons of fish by a special method if the markets will not take them, or if our methods of transport do not conform to the scheme.

It remains to be said that, in the British Isles, the problem is mainly how to get the fish to the markets in a fresh state. Cold storage methods will help this, but the wider researches are required for the fishermen who go far to sea, and also for fish imported in a frozen state from our Colonies.

With respect to the second section, the preservation of both fruit and eggs, if properly understood *and applied*, would mean a great saving of wealth to the country, and could also only mean better health. It seems very doubtful, at the moment, if new laid eggs will ever again sell in any part of the country at 6*d.* a dozen; such a low figure was reached in the past, due to a prolific season and with no knowledge or means of keeping them fresh available to the farmer.

With respect to fruit, refrigeration has enabled this country to enjoy a perpetual autumn; but the methods that enable Australian fruit to be eaten in a sound condition in this country are not applied to home grown fruit. Why?

The fruit merchants of this country have had to depend on the pure science of countries other than our own to help them to keep material whose life history has not been finished.

* See Appendix III.

Fruit and vegetables offer an immense field for research.

The third section, milk and its products, opens up a still greater field—a field that should be made either national or municipal or both.

Nature never intended milk to come into contact with air—the penalties attached to breaking this rule are very great.

Sterilization as usually adopted hopelessly destroys its structure, and, no doubt correspondingly destroys its food value. Common-sense deductions point to mechanical milking into covered vessels, the whole to be cooled down to 3° or 4° C. as soon as possible after the milking operation, and then kept away from the air till the time of consumption.

The municipality of Paris adopted these methods for infant feeding, and has—or at least had, before the war—its own farm on the now historic Marne.

Milk so treated and kept cold will keep quite sound, with ordinary commercial handling, for over a week—theoretically, it should last for months. Why, then, are not these fundamental facts employed and insisted upon?

The proper methods of making and keeping of butter and cheese render it essential to adopt low temperatures, so that milk and its products require special attention from the refrigerating point of view, and concern the nation in a most vital part—infants and invalids.

The few problems selected must only be regarded as typical, the number awaiting solution, including engineering, are almost legion.

In chemical, industrial, agricultural, horticultural, brewing, and manufacturing operations, refrigeration is already employed, but to an absurdly limited extent. A proper knowledge of low temperature effects would lead to great developments. This can be said without the slightest hesitation.

Wheat * (and other cereals), if stocked in this country in "reserve" quantities, will require very special attention in storing. Wheat belongs of course to the second section, the life history not being finished, and it will stand low temperatures particularly well, while its parasites would be either killed off, if existing, or prevented from forming. Further, wheat kept dry and cold would be in an ideal condition for long period storing.

The main questions may now well be asked: What has stood in the way of scientific development in the past, and what are the suggestions for the future?

* See Appendix II.

With respect to low temperature work, the answer to the first question can be readily divided into two main reasons:—

(1) The want of a bond or link between pure science and industry.

The present time is most opportune, and if the man of science will only realise that laboratory results are not by any means conclusive, he will find the man of commerce will help him in researches of a practical nature; the net result will be more commerce and a higher and better scientific knowledge.

(2) The man of science has not had facilities in his laboratory for low temperature work. Many researches stop short at the melting-point of ice or a little below.

Every seat of scientific learning should have a refrigerating apparatus as part of its equipment —not a toy machine, but a self-contained cold storage with arrangements for a "cold" reserve (large quantities of calcium chloride brine) for periods of interruption. No research of any kind where temperature is a function can be considered complete that does not go down to the lowest limit reasonably obtainable, yet how many institutions are there where such investigations are possible? The lack of such facilities in the light of recent advances all over the world, will constitute a serious disadvantage to our men of science, and the question must be taken up by every scientific body in the kingdom.

The suggestions as to the future are partly answered, but only partly.

If every scientific institution in the country was provided with adequate low temperature installations, there would still remain, from the cold storage point of view, the want of that link which is missing at the moment. This link will, no doubt, be forged by the Advisory Committee of the Privy Council on Scientific and Industrial Research, whose particular and important function is to promote research and *weld science to industry*.

The Cold Storage and Ice Association is working in close touch with this Committee, and has intimated its willingness to give any practical help in the way of publishing results.

The Association of Cold Stores Proprietors and Managers, and also the British Engineers' Association, have also expressed themselves as being interested in low temperature research work, and both have also been in communication with the Advisory Research Committee.

The Institution of Mechanical Engineers have a standing Refrigeration Research Committee,

whose first report contains suggestions for a unit of refrigeration (one calory per second) and a standard unit refrigerating machine, which, no doubt, will become the British standard.

The War Office, Board of Trade, Board of Agriculture and Fisheries, Ministry of Munitions, Admiralty, Ministry of Food (with its special section of Cold Storage and Inland Transport of Food), Local Government Board, Ministry of Reconstruction, Ministry of Shipping, and the Board of Education, are all more or less affected by the cold storage problem. In short, it is a matter of urgent national importance, but inasmuch as it has been previously shown greatly to affect our Colonies, it becomes an Empire matter.

The cold storage industry then, has a great claim on science; but low temperature study, education and research touching so many Government Departments, and with such boundless possibilities for so many branches of science, commerce and industry, and also for Empire development, it is fitting that the Royal Society of Arts should take the matter into its own consideration.

The author therefore suggests:—

(1) That institutes of research and schools of refrigeration * be instituted in London and Liverpool. (This suggestion has been approved by the Cold Storage and Ice Association.) These institutes would be attached to learned institutions, and would act as centres for research work and the higher instruction of graduates (or others duly qualified) in medicine, science, engineering and veterinary science from home and colonial universities. They would also keep definitely in touch with Government Departments and associations interested in low temperature work.

(2) That every seat of scientific learning should provide facilities for low temperature study and research.

(3) That every engineering school of university rank should provide facilities for refrigerating engineering study and mechanical research.

(4) That the principal technical colleges and schools under the Board of Education should be provided with facilities for instruction in mechanical refrigeration.

It remains to be said that we are the only country in the world where the purely scientific side of cold storage work has been neglected—happily, it would appear as if this stigma was about to be removed.

I am authorised by Sir Frank Heath, of the Department of Scientific and Industrial Research, to announce that the Government intend to take up research as applied to Cold Storage in a comprehensive manner.

* See Appendix IV.

APPENDIX I.

The actual values of the principal foodstuffs imported, subject more or less to refrigeration, were in 1914 as follows:—

Beef	£19,060,371	
Mutton	11,410,310	
Pork	2,360,722	£32,831,403
Rabbits	747,643	
Bacon	18,225,568	
Hams	3,063,078	
Meat (unspecified)	1,693,984	
Poultry and game	943,726	£24,673,999
Total for meat		£57,505,402
Butter	24,014,276	
Cheese	7,966,162	
Eggs	8,652,850	
Fruit	11,118,051	
Hops	558,741	
Lard	4,750,943	
Margarine	3,077,361	£60,138,384
Total		£117,643,786

The most interesting comparative import figures are:—

	1914.	1915.	1916.
	£	£	£
Poultry and game	943,726	637,852	668,407
Butter	24,014,276	27,022,745	18,977,450
Cheese	7,966,162	11,107,100	12,945,450
Margarine	3,077,361	5,751,253	8,983,007

APPENDIX II.

The following figures, taken from the Royal Society's report relating to the "Food Supply of the United Kingdom for 1916," supplements the information given in Appendix I., in conveying the magnitude of the perishable produce trade. The quantities are metric tons, and deal with home as well as imported produce:—

Description.	Average, 1909-13.	1916.
Cereals	4,865,000	5,074,000
Meat, poultry, game, and lard	2,848,000	2,555,500
Milk	4,500,000	4,350,000
Butter	321,000	229,000
Margarine	118,600	235,000
Cheese	147,000	110,000
Condensed milk	55,200	57,390
Eggs	258,000	195,000
Fish	848,400	470,000
Vegetables (other than potatoes)	1,232,000	989,820
Fruit	1,271,000	1,014,000

APPENDIX III.

The great value of fish as a food, and the particular value of herrings, merits attention being drawn to the following figures, extracted from the *Fish Trades Gazette* for October 20th, 1917, and shows that by far the greater weight of herrings landed in 1913 were *exported* :—

		(1913.) cwt.
Landed from British fisheries . . .		12,183,000
Exported fresh . .	cwt. 1,167,000	
" cured . .	" 8,795,000	
		9,902,000
Balance . .		2,221,000
Fresh herrings imported		1,236,000
Available for home consumption .		3,457,000

In October, 1913, the herrings landed per day at Yarmouth averaged 65,000 cwt.—an astonishing total.

APPENDIX IV.

Refrigeration forms an optional subject in the Honours, or fourth year of study (post Graduate to Ordinary degree), in Mechanical Engineering, under the Faculty of Engineering, University of Liverpool.

No scheme has yet been possible on lines similar to those laid down by the French Association of Refrigeration (Special Committee report, October, 1910), which was to the effect that a Diploma of Refrigerating Engineering be established, open only to candidates with an approved degree, or who can otherwise "justify five years' constant industrial practice in some manufacture."

The scheme included attendance on lectures given at the High School of Aeronautics and Engineering (Paris), in the following subjects, each subject being under a separate professor :

1. Science of Refrigeration.—Subjects: (*a*) Theory of Physics ; (*b*) Mechanics and Thermodynamics; (*c*) General and Biological Chemistry; (*d*) Mathematics ; (*e*) Legislation.

2. Refrigerating Machinery.—Subjects: (*a*) Practical Physics ; (*b*) Refrigerating Plants ; (*c*) Building and Insulating Materials.

3. Applications of Refrigeration.—Subjects: (*a*) Hygiene ; (*b*) Food ; (*c*) Mining, Metallurgy, and Public Works ; (*d*) Agriculture and Agricultural Machinery ; (*e*) Physical and Chemical Industries : (*f*) Application and Use of very low Temperatures.

In the report the actual professors suggested are named.

It would appear that the schools or institutes of refrigeration proposed for this country could, with advantage, adopt a similar syllabus. Such interworking is absolutely essential for successful research and instruction in such a subject as refrigeration.

DISCUSSION.

MR. GILBERT ANDERSON, in opening the discussion, said a great deal was heard about the want in this country of scientific research, but in his opinion no country had attained such high eminence in scientific research as Great Britain had. It was owing to the researches made by British scientists, chemists and engineers, that the problem of refrigeration had been successfully solved. That problem had been solved thirty-five years ago by British brains and British energy, but from that time to the present day the Government had rendered no assistance whatever to it, although no other country in the world was so dependent upon refrigerated food. All the frozen meat that came to this country from New Zealand was submitted to veterinary inspection there, but there was no kind of inspection laws here. It would be an excellent thing to have an international system of meat inspection. In this country investigators worked in water-tight compartments, and there had never been any link between scientific research on the one hand and merchants on the other. Merchant adventurers many years ago took up the question of refrigeration and had the necessary machines built, and made arrangements for supplying the people of this country with frozen meat. If it had not been for that frozen meat the Government would never have been able to carry on the war, and yet the Government had not made up its mind to refer the question of cold storage to one particular department, as it ought to do. Refrigeration covered very many branches, and the whole question needed to be studied in all its aspects. The moment life was taken away from an animal, bacteria became active and decay set in, but it was not yet known exactly what decay of meat meant —how it went on and how it was to be prevented. Then there were the mechanical changes to be considered in the structure of the tissue. Another question that needed to be investigated was why there was a depression of the market in frozen meat every now and then, and so much waste in other things, such as fruit and eggs. No animal should be permitted to be killed for food in this country except in a municipal abattoir under proper supervision, and in connection with those abattoirs there should be cold storage facilities and proper plant for utilising the by-products. He hoped it might be possible to induce the Government to let one particular department, say the Board of Agriculture, take up the question of cold storage.

MR. CHARLES J. TABOR said he was glad the question of refrigeration was being brought to the notice of the public, because many people still

thought it was a chemical and not a mechanical one. As the founder of the frozen rabbit trade, about three or four years after the advent of refrigerated meat, he had had a very wide experience in the subject. Shortly after that he was appointed one of Lloyd's surveyors, and he soon saw that it was not only his duty to save the underwriters from heavy claims, but also to find out the reason for the damage that occurred to the goods. He had made some very wide researches into the growth of mould on refrigerated produce, and he was glad to find that scientific people had now taken the matter up. That mould could be prevented if equable temperatures were maintained. As the author had said, some food substances required different temperatures from those required by others. The chief point to be remembered was that both freezing and thawing operations required to be carried on slowly. The whole process of freezing consisted of disintegration; all food substances, meat even more than fish, contained a large proportion of water, and its violent expansion at the time of freezing must of necessity cause rupture of the tissues. He did not think fish could ever be advantageously frozen, because, although frozen fish was quite wholesome, from a gastronomic point of view it was very much injured in the process.

Mr. Charles Chamberlin said he would be glad if the author could state whether the fruit put on board ship in a South African port had an opportunity of having the heat removed from it. The expense of bringing fruit from South Africa had been very great, owing to want of knowledge of how to treat it, and the difference in the condition of different cargoes of fruit when they arrived in this country was very noticeable. He would like to know the reason for that. The fruit was inspected by the authorities before it was put on board, but it was not everyone who had the facilities for cooling it before it was shipped, and when the fruit arrived in this country it was often in a soft condition. A complaint was frequently made, chiefly with regard to peaches, that the fruit was rotten in the middle. He did not think that was due to decay. The solidity of the matter that was frozen was not the same, the stone of a peach being about 80 per cent. harder than the flesh. When the fruit was exposed to the normal temperature the flesh became of that temperature, but the stone inside remained cold and hard for days after it came out of cold storage. The action of the cold stone on the soft flesh produced what people usually called decay, but the question was whether it was decay or merely the action of the cold stone on the soft flesh. When fruit was put into cold storage it should not be in too immature a state nor should it be put in ripe. He did not think it was yet known how to bring fruit to this country in perfect condition.

Mr. J. Thom thought that insufficient attention was paid to the subject of cold storage from an educational standpoint. The science of that subject was not different from other sciences taught in schools and colleges, as it approached closely to the subject of heat, and the mechanical part of the subject was the only one that did not fit in with the ordinary subjects studied in colleges. He thought it was quite possible for technical classes on refrigeration to be started in the principal technical colleges and schools, as suggested by the author, especially in view of the fact that this country was very dependent for its food supplies on cold storage.

Mr. F. W. J. Moore thought the remarks made by Mr. Chamberlin showed the necessity for some systematic method of research into the question of low temperatures. If an article could be frozen it was simpler to deal with than another product which must not be frozen. He had been connected with the cold storage of fruit ever since the subject was first brought forward, and he thought the question of temperature had been neglected far too long. More was known about the matter now, and it was realised that certain fruits would keep if the temperature was low enough. Apples, for instance, would not suffer even at 32 degrees, but fruits coming from the Cape were very different articles to deal with. With regard to Mr. Chamberlin's remarks about the stone affecting the fruit, as a practical fruit canner he knew that difficulties were experienced in canning fruit containing stones, and there might be some trouble arising from the stones when carrying fruit at low temperatures. Certain fruit such as peaches, apricots, plums and oranges, should be pre-cooled, but he did not think it was necessary in the case of apples. Research was certainly required into the question of temperature, and he agreed with Mr. Gilbert Anderson that the Government should hand the matter over to one particular department. Such things as hops and tobacco would be very much improved if it was known in what temperature they should be kept.

Mr. George Daniels said the paper dealt largely with research applied to foodstuffs, which, in view of the present shortage of food and the possible future world shortage, was very important, but research should also be carried out in the other branches of the subject such as the engineering and chemical branches. The work had up to the present been more or less fragmentary, there being no system by which those dealing with the various aspects of the subject—physical, chemical, and engineering—could all work together. He thought very good results might be obtained by the establishment of schools of refrigeration in various parts of the country, as had been suggested. Personally, he was concerned more particularly at the present time with refrigeration applied to the

chemical industry, and there practically each case brought out special problems of its own, for the solution of which all the various periodicals had to be studied in order to find out what different men had done. One use to which the schools of refrigeration might be put would be to collect and co-ordinate those data which had been obtained in the past, and might be obtained in the future, and keep them together in a handy form for the benefit of those engaged in the refrigeration industry. The need for research was clearly shown by the fact that when, about two and a half years ago, his own firm wanted to put up a plant in connection with chemical work for war purposes, and had to go down to a temperature of -50 degrees Centigrade, they were only enabled to carry out the work by the use of certain thermo-dynamic data published by the Royal Society. The proposed refrigeration schools might also be used for instructing the public, many people still being prejudiced against cold stored food, and for overcoming the diffidence displayed by many manufacturers towards correct scientific work.

THE CHAIRMAN (the Hon. Sir Thomas Mackenzie, K.C.M.G.), said that fifty years ago the Society of Arts set up a committee to investigate the subject of refrigeration, although it seemed to have lapsed about 1881. Speaking as one from abroad, he was surprised that this country, depending, as it did, to such a large extent upon food supplies from abroad, had not been able to move its Government to act in the matter. The scientific men, manufacturers and business men of this country were second to none, and yet there was that missing link which it seemed impossible to find. The Dominions overseas did not possess the scientific men that this country had, and the people there had had to pick up their knowledge as best they could, and department after department was established for the purpose of furnishing such information as that which had been asked for by Mr. Chamberlin. New Zealand had not yet developed her fruit industry, but in the dairy industry butter and cheese were being manufactured and exported which previously it had been impossible to export. The Government had stepped in and appointed instructors, and until war broke out they had employed scientific men in this country to report on the condition of the butter and cheese that arrived here. Those scientific men reported to the instructors and experts in New Zealand, who informed the managers of the dairy factories if anything was wrong with their produce. The instructors and managers would unite in trying to discover what was wrong, and they were usually successful in doing so. In the Colonies people had had to depend upon their own efforts and fight their own way through difficulties. He hoped that the paper read that afternoon, and the remarks made by the speakers in the discussion, would have some fruitful result, and that the Government would be induced to take the matter up seriously, and supply the missing link between science and industry.

ALDERMAN MORGAN HOPKIN suggested that a resolution, emanating from the Chairman, should be passed by the meeting requesting the Prime Minister to receive a deputation of gentlemen from the Royal Society of Arts on the subject in question, which was one of Imperial importance.

THE CHAIRMAN said he had no doubt the Society would take into consideration the suggestion made by Mr. Hopkin, but he did not think it was his duty to move in the matter, which was a purely domestic one for this country.

PROFESSOR WEMYSS ANDERSON, in reply, said that the questions asked by Mr. Chamberlin about the cold storage of fruit showed the great need there was for research. He thought that as a matter of fact pre-cooling was of benefit in dealing with all kinds of fruit. Nature seemed to indicate that if the fruit was to be kept by refrigeration at all it ought to be cooled down as soon as possible. With regard to the question whether the trouble in cold storing stone fruit was due to decay or the action of the stone, nature of course intended that the stone should be reached by the outer covering eventually breaking down, and, if the outside was prevented from decaying in the ordinary way and breaking up so as to free the stone, nature tried to find some other way, and it would be found that the apparent decay was undoubtedly the breaking-up of the tissue which occurred from the inside and spread from the stone outwards. In fruits where there were such entirely dissimilar materials as the outside structure and the stone, such breaking up from the inside outwardly often took place. He agreed that research was also needed with regard to temperature. When once cooling was commenced the temperature ought to be kept as even as possible; the steadier the conditions the better. He agreed that work in the past had been carried on far too much in watertight compartments, and he hoped that the co-ordination of research would soon be taken in hand.

A vote of thanks to the author for his interesting paper was then proposed by the CHAIRMAN, and carried unanimously, and the meeting terminated.

CULTIVATION OF THE WOOD-OIL TREE IN UNITED STATES.

Several years ago the United States Department of Agriculture undertook the study and experimental cultivation in that country of the Chinese wood-oil tree, with encouraging results. It found that the tree grew and fruited well in South Carolina, Florida, Alabama, Louisiana, Mississippi, Georgia, Texas, and California, but

could not fix the northern limit of cultivation in the United States in the absence of data as to how low a temperature the wood-oil tree will stand without injury. However, the tree has withstood a temperature as low as 4° F.; and as it drops its leaves in winter and does not wake up early in the spring, it is not likely to be injured by late frosts. To quote further from the Department's bulletin on the subject:—

"The Chinese wood-oil tree (*Aleurites fordii*) is probably not very long-lived, and would be comparable in this respect to the silver maple. The flowers come out before the leaves; they are fully as large as catalpa flowers, and the tree in bloom is a very pretty sight. As an ornamental tree the wood-oil is likely to prove about as desirable as the catalpa, but the soft wood is of little value, and, like many other soft-wooded trees, the branches break off easily in heavy winds.

"The tree commences to bear fruit when four or five years old. The fruits are the size of small apples, and contain from two to eight large, oily seeds that are reported to be poisonous, and should not be eaten. They at least have a purgative effect similar to that of the castor bean, to which the wood-oil tree is botanically distantly related.

"The value of this tree lies in the fact that the nuts contain one of the best drying oils, called wood or tung oil. In recent years this oil has revolutionised the varnish industry of the United States, for it has made possible the manufacture of a quick-drying varnish that is less liable to crack than that made from kauri gum. Tung oil has also been found of special value in waterproof priming for cement."

The bulletin then discusses cultural methods, probable cost of land and labour in the United States, and estimated yield, and continues:—

"In starting an oriental industry in America the most important factor to be considered is the amount of hand labour involved. There does not appear to be much involved in this industry, as the gathering and husking of the fruits seem to be the only handwork required. Further, the American farmer has the advantage over the Chinese of cheap, accessible lands and team labour. Since the hand labour required in a well-planned orchard is not great, it would seem to be entirely possible, by the systematising of such an industry on large plantations, to produce wood-oil more cheaply in the United States than it is now produced by the wayside plantings in China, which must be very wasteful of human labour.

"The prospects are that there will be a continual and growing demand for wood-oil. The increased use of soya-bean oil, it is reported, will tend to augment, rather than to diminish, the consumption of wood-oil, as soya-bean oil dries too slowly, and requires the addition of wood-oil to help it dry. The home demand in China is likely to expand, and the opinion of American importers of the Chinese product seems to be that the American-made oil could meet the requirements of the United States market. If it does, 40,000 acres of trees would be required to supply the present demand.

DEVELOPMENT OF NEW PROCESS FOR UTILISING PETROLEUM RESIDUES.

One of the notable features in the current general expansion of American chemical industries is the evolution of the Rittman process for transforming a large proportion of the residues of petroleum refineries into gasoline, benzene, and toluene. According to a report by Mr. T. H. Norton, United States Commercial Agent, the process, originated in the Bureau of Mines and elaborated as an industrial method under the auspices of the same Bureau, has now issued from the experimental stage and taken its position as a recognised industrial asset in the national cycle of productive activity. By its aid vast quantities of petroleum waste, hitherto available for little beyond fuel purposes, can be transformed at will either into gasoline for use in motor engines or into benzene and toluene, also susceptible of the same utilisation, but constituting likewise the crude material for the manufacture of the two coal-tar high explosives, picric acid and trinitrotoluene, and forming also the starting points for the synthesis of an almost endless variety of dyestuffs, medicinals, photographic chemicals, artificial flavours, and perfumes.

Under normal conditions in times of peace the by-products of American coke ovens can more than meet the national demands in the manufacture of the latter categories of chemicals. The case is, however, far different in regard to the supply of motor fuel. Apprehension is felt that at an early date the supply of gasoline from crude petroleum, or of benzene and toluene from the distillation of coal, may fall far behind the world's demand for motor fuel. The Rittman process promises to relieve entirely this anxiety, or, at least, postpone all danger of a shortage to a very distant date. Economically it will act as a healthful check upon any unnatural tendency to increase the price of ordinary gasoline. The process, as now perfected, makes it possible to produce gasoline at a cost of 6 cents (3*d.*) per gallon. This figure may be contrasted with the wholesale rate of 22 cents (11*d.*) per gallon for gasoline obtained directly from petroleum refineries.

The process is thoroughly protected by patents. Manufacture in the United States is permitted without payment of licence fees or royalties. Manufacture abroad is permissible under the patent rights secured in the different countries on the payment of fixed licence fees. The

American company controlling the patents is actively engaged in introducing this new and distinctly American process in the leading foreign countries, where its advent is warmly welcomed.

There is, it is added, every indication that, at an early date, the American Rittman process will be well installed in all lands where petroleum refineries exist, and will exert a widespread influence upon the rapid evolution of all phases of transportation—terrestrial, aerial and marine—dependent upon an abundant supply of gasoline.

INDIA'S SHARE IN THE RICE TRADE OF THE WORLD.

The *Bulletin of the Imperial Institute* contains an article on the production and uses of rice. Practically all the rice-producing countries of the world are considered separately, in respect both of their rice crops and of their trade in rice, and an attempt is made to arrive at some idea of the world's production of this important foodstuff. It is calculated that the output of cleaned rice in 1916–17, in all countries except China, amounted to about 60,000,000 tons. Of this the British Empire produced about 36,000,000 tons, mostly in India, where the crop (including an allowance of a million tons for native States) was no less than 35,000,000 tons. Of the foreign production of 24,000,000 tons, over 20,000,000 tons were grown in five countries — Japan, Netherlands East Indies (chiefly Java), French Indo-China, Siam, and Korea. Estimates of production in China are largely guesswork, but the Imperial Institute, adopting the view that the output in China is not likely to be much inferior to the Indian crop and may exceed it, concludes that 40 per cent., or a little less, would be a fair allowance for India's proportion of the world's annual production of rice.

No less important is the position which India occupies in the world's rice trade as a source of supply for other countries. That is not a necessary consequence of its importance as a rice producer. Some of the countries of largest production—China, Japan, Netherlands East Indies—do not grow enough to supply their own needs, though in the case of Japan the large increase in the rice crops in the last three years has changed a heavy import balance into an export balance, so far as the trade with foreign countries (excluding Korea and Formosa) is concerned.

The world's export trade in rice is practically under the control of three countries, India, French Indo-China, and Siam. It has been calculated that the quantity of rice which entered into international trade, as shown by the export returns of different countries, amounted in 1913 to about 6,400,000 tons. This includes exports from European countries of rice which has been milled in those countries, which came originally from India, Siam or Indo-China, and which unduly swells the total by being counted twice over. Even so, the original exports of rice from India amounted to 40 per cent. of the total, while those from Indo-China were 20 per cent., and those from Siam 18 per cent.; in other words, these three countries provided nearly four-fifths of the total.

India's export trade in rice is really dependent on Burma. Not only does Burma provide about three-fourths of the exports of rice from India as a whole (1,835,000 tons out of 2,420,000 tons in 1913–14), but Burma usually sends to other provinces of India more rice than those other provinces export. Without Burma, India would not be self-supporting in rice. As it is, India's exports of rice in the year before the war were equal to the gross requirements of the rest of the Empire, though actually only 42·6 per cent. of the exports went to British countries, and 57·4 per cent. to foreign countries.

The exports direct to the United Kingdom were only between 6 and 7 per cent. of the total. On the other hand, the United Kingdom imported considerable quantities of rice from Holland and Germany which had been first exported from India to those countries, and after being milled and polished there had been re-exported to the United Kingdom.

Rice-milling, at one time a flourishing industry in the United Kingdom, had declined before the war owing to severe competition from the Dutch and German mills, with the result that not only was the British home market partly supplied by foreign-milled rice, but what was at one time the considerable British export trade in fully-milled rice had been reduced in many directions. Since the war both the home and export trade in milled rice have been largely recovered by the British rice-millers, and it is hoped that this industry and trade may be retained after the war. The possibilities of the development of the complete milling of rice in India before export are also a matter for consideration.

The second part of the article deals with the uses of rice both as an article of food and for industrial purposes; the value of rice meal as a feeding-stuff for livestock is also discussed. The milling processes are described, and the different grades of rice and the by-products which are obtained are shown in diagrammatic form. Numerous composition tables are given, and comparisons are afforded in this respect between rice and its by-products and other foodstuffs.

In connection with this subject it may be pointed out that the Indian Committee of the Imperial Institute is now conducting, at the request of the Secretary of State for India, an inquiry into the possibility of increasing the use

of Indian raw materials and foodstuffs within the Empire. The inquiry naturally involves an investigation of the extent to which other countries, and especially enemy countries before the war, had secured a predominant share in Indian trade, and the causes which led to this condition.

A special committee has investigated the trade in rice, and it is understood has now almost completed its work. The need for such an inquiry is clear from the facts mentioned above regarding the dominant position taken in the rice trade by Germany and Holland, before the war, as compared with the United Kingdom.

ARTS AND CRAFTS.

Serbo-Croatian Art at the Grafton Gallery.—The exhibition of Serbo-Croat art at the Grafton Galleries is interesting from many different standpoints; but if its attraction is in some measure political, its appeal as an exhibition is primarily from the side of art; and though the art in the first three rooms happens to be represented by sculpture and painting, and only the long room is given up to arts and crafts, the whole gallery may well be described as devoted, in the widest sense of the term, to decorative art. The sculpture claims notice in the first place. The collection exhibited at the Victoria and Albert Museum in 1915 proved that, however much critics might disagree concerning the value of the works of Ivan Mestrovic, there was no doubt that his whole outlook on art was intensely decorative. There is in the present collection nothing in the way of purely decorative work which compares with the roundel commemorating Kossovo, or some of the large vases which were shown in the earlier exhibition, though the plaster cast of the shield for the Crown Prince of Serbia is a fine work of its kind; but there is a far larger proportion than at South Kensington of reliefs in plaster and wood, and it is this work which is of peculiar interest from the decorative point of view. Not only are certain of the exhibits, such as the two angels' heads—one of which stands on each side of the rather painful wooden statue of the Crucifixion—beautiful in feeling and decorative in handling, but the technique is worth the consideration of all those who have to do with sculpture in wood. The treatment is flat and conventional, there is no undercutting, the whole thing is characterised by an extreme simplicity, and the result in most instances is something really remarkable. There are, it is true, cases in which the tool marks seem to have been unnecessarily and unduly accentuated, so as to produce a mottled effect not unlike the punching in certain types of Western European work, which is not wholly pleasing. Further, if the style of the great Serbo-Croat sculptor were consciously imitated by British artists, it would probably lead to disastrous results; but for all that there is a great deal to be learnt from him by those who have the seeing eye. The work of T. Rosandic, the only other sculptor who exhibits, suggests that he is a pupil of Mestrovic, or at least a disciple. It shows no signs of real independence and originality. He exhibits, besides a collection of larger pieces, one or two specimens of jewellery, but there is nothing very remarkable about them. The paintings are all by Racki, and for all their grim realism they are, especially those which illustrate Serbian legends, conceived in a truly decorative spirit. The grouping of the figures, the distribution of the masses, and so forth, strike one at once, long before one is near enough really to understand the subject. The decorative objects in the last room include some beautiful Bosnian damascening, which recalls some of the work from Bosnia-Herzegovina, shown at the Paris Exhibition of 1900, and some remarkable jewellery from Bocche di Cattaro, lent by Sir Arthur Evans. Among the objects for sale are a quantity of dolls, beautifully dressed in the national costumes of the various parts of the Balkan Peninsula and specimens of the work done by the Serbian refugees in Corsica. The embroidery is, as usual, very characteristic—most of it obvious Slav work, with dashes of something which makes us remember the constant neighbourhood of the Turk in the native lands of the workers. There is also a little basket work and some leather work in the shape of slippers, with fronts of cut leather of various colours, such as are worn by the peasants. The exhibition will be open until December 22nd, and it is an event which no one interested in art or arts and crafts can afford to miss.

Messrs. Ramsden and Carr's Exhibition.—The exhibition of the works of Messrs. Omar Ramsden and Alwyn Carr—held annually at this time of the year in St. Dunstan's Studio, Seymour Place, Fulham Road—has for many years past been one of the most important shows of silversmiths' work held regularly in London, and although since the early days of the war Mr. Carr has been in France, and though one hardly expects much work of this kind to be done nowadays, Mr. Ramsden had managed to get together quite a big collection of work this year at the beginning of December. There were not, of course, so many large and important objects as used to be on view in pre-war days, but there was a goodly collection of work none the less. One of the finest pieces was a loving cup, very simple in its main lines, and depending mainly upon its shape for its distinction, but with richly ornamented bands on the stem and round the cover. Another outstanding work was a cup designed as a trophy for a lambing competition. The most imposing piece of ecclesiastical silver work was a large chalice for Winchester College Mission, and there were also some copper and brass almsdishes, vases, and ewers, which were well worth attention, and a couple of well-shaped, spaced and well-lettered

designs for memorial brasses. Amongst the domestic objects may be noted an extremely practical and well-portioned circular dish for *hors d'œuvres*, or cheese and butter—planned to hold three glass dishes, and furnished with a broad flat handle, easy to grasp and good to look upon. Nothing could be simpler in design, but the simplicity was that of a real work of art. A cream (or should we say nowadays, milk?) jug, with a very deep lip and a well-arranged handle, was another happy combination of practicality and art. But, indeed, all the exhibits were, as usual, characterised no less by workmanlike than by artistic qualities. That, of course, should always be the case, but unfortunately objects intended for common use which are labelled "artistic" are too often by no means well fitted for the purpose to which they are supposed to be put, and one is proportionately grateful to find work which, like this, is not only beautiful and decorative, but eminently fit for its purpose.

CORRESPONDENCE.

TECHNICAL TRAINING FOR DISABLED SOLDIERS AND SAILORS.

I receive a large number of letters and inquiries from County and Local War Pensions Committees outside London, which prove that there is not sufficient information to hand as regards the training of disabled soldiers, especially in connection with the proper selection of men for suitable trades; there seems to be a lack of suitable panels of employers and workmen to advise those Committees as to selection of men, and information as to whether certain trades will be willing and able to employ the men when they are trained. Unless something more is done, there may be danger that these men may not find employment in the industry for which they have been trained. As an instance of careful selection of men for particular trades, I may mention the case of a man who was recommended for printing. On interviewing the man, I found his reason for choosing that trade was, that he had before the war been a platen hand in a printer's, and for that reason believed he should take up machine printing, of which he really knew nothing. On further questioning him, I found that a doctor had told him he should take up some occupation which would bring him more or less in the open air. Machine printing was an undesirable occupation for him for that reason alone, because the atmosphere of a machine room is close and confined. Moreover, he had an injury to his leg which rendered him not sufficiently strong for the heavy work and continued standing. I recommended him to take up carpentry and joinery, for this would be lighter and give him chances of going from job to job in a better atmosphere.

I agree with what Major Tudor Craig said about the importance of keeping men as far as possible from taking up fresh trades if they can be kept in their own trade, especially with a little extra training, and give the following as recent examples which have come under me personally:—

Two engineering men, unable to follow their trade because of their disability, were sent to be trained as dental mechanics. They were both intelligent men with good workshop experience, and I advised them to train for the engineering drawing office, for which they would be well fitted after the training which we are now giving them.

Further, I am in accord with what Mr. Myers said about the advantage the soldiers at Roehampton have by the stimulating effect of a number of men training together. I therefore feel that the County and Local War Pensions Committees near London should co-operate, and seek to obtain training for men in London institutions, in order that a fairly large number of men may be trained together for a particular trade. This will have a stimulating influence on the men, and would decrease the cost per man for training.

Lastly, a word on broad training. We must guard against the great danger of narrow training, and not be led away by war-condition demand for men who with short training can now find employment. The men must receive broad and efficient training so that they can hold their own in peace time and be able to adapt themselves to changing conditions of industry. For example, I am asked to train men for acetylene welding, for which there is a great demand now, but such training alone would probably be insufficient and inadvisable from the point of view of stable employment in peace time. The men should be trained in some branch of metal-working, in addition to acetylene welding, if they are to be able to earn their living. They will then become better acetylene welders. Broad and sound training must be the motto, especially for fitting the disabled soldier to hold his own in the future.

C. T. Millis, Principal.

Borough Polytechnic Institute,
December 14th, 1917.

I regret that I was unable to remain for the discussion on Lord Charnwood's interesting paper on Wednesday last, as, if the opportunity had been afforded, I should like to have drawn attention to the excellent work being done by the Canadian Hospitals Commission for disabled and invalided men returning to Canada. That work so commended itself to Sir Rider Haggard, on the occasion of his visit to Canada early last year, that he characterised it as "an example to the Empire." At that time, however, the Commission had scarcely got into definite shape, but its scheme of work was so good, and its plans so well formed, that Sir Rider was satisfied it would be, as it has since proved, a great success.

There are various features of interest in the work of the Commission to which it would be well for our home authorities to give attention, as the experience gained in Canada may be of considerable value to us here. But the one that I have

specially in view is that which formed the subject of Lord Charnwood's paper. In an address delivered at the National Conference of Social Work held at Pittsburgh, U.S.A., recently, the Secretary of the Commission (Mr. E. H. Scammell) said "it was early recognised that the provision of hospitals and homes was not the whole duty of Canada to her men coming back from the war—that they needed work and training." To give effect to this idea, vocational training or re-education classes have been started in all convalescent hospitals and homes, at which the rudiments of shorthand and typewriting, mechanical drawing, woodworking, gardening, poultry-keeping, motor engineering, and a large number of other subjects, are taught. For the necessary instructional purposes, vocational officers have been appointed and Disabled Soldiers Training Boards have been established. On this subject, the reports of the vocational officers of the various provinces concerning the work done from April 1st, 1916 to May 1st, 1917, given in the last report of the Commission, are well worth studying by our own educational and hospital authorities. "Vocational training in the hospitals is necessary," according to the experience of the Commission, "not only because of its educational value but because of its therapeutic value," an opinion fully confirmed by Lord Charnwood and other speakers at the meeting last week.

There is another matter of special interest to us just now, in which the action of the Canadian Hospitals Commission and their experience may be of value; that is the arrangement for finding employment for disabled and discharged men. In all the Canadian provinces, provincial employment commissions have been established, nearly all of which have large numbers of local committees. The result of these appointments has been most gratifying, and may furnish important and useful information to the various ministries of our own Government who are charged with the duty of finding openings for disabled men.

E. T. Scammell.

NOTES ON BOOKS.

Arithmetic for Engineers. By Charles B. Clapham, B.Sc. London: Chapman and Hall. 1916.

Mr. Clapham, in his preface, apologises for his title, and not without reason, for his book goes far beyond the limits usually assigned to arithmetic, and its use need by no means be confined to engineers. However, modesty is an unusual characteristic of authors, specially of authors of school books, so there is not much fault to be found with the title, and still less with the contents of a very useful and practical text-book.

The only previous knowledge the author assumes in his readers is a knowledge of the first four rules of arithmetic, and if any students are to be found who lack the necessary information they need not be discouraged, for they will find all they want in the book itself.

The characteristic of the book is that the author throughout deals with concrete things, not merely with numbers; and even the simplest propositions are expressed graphically. Thus to explain a vulgar fraction he gives us a diagram of a unit divided into parts, so that you can see for yourself that $\frac{3}{4}$ means three of the four parts, and $\frac{13}{23}$ means thirteen of the twenty-three parts into which the unit is divided. In like manner it is graphically shown that $\frac{3}{4}$ (of a unit) is really the result of dividing three units by four units. And so throughout the book the student is led to think not of ideal numbers, but of actual concrete volumes and magnitudes.

After two chapters on vulgar and decimal fractions, Mr. Clapham leaves arithmetic pure and simple, and goes into algebra, for his three chapters—"Symbols and their Uses," "Simple Equations," and "Transposition of Formulæ"—are frankly algebraic and nothing else. But the algebra is treated in a very unusual fashion. Put roughly, it may be said that Mr. Clapham tells his students that a vast number of mathematical calculations may be simply carried out by the use of symbols and formulæ which do not necessarily require translation until the result is attained. The statement in this shape (which is not to be fathered on the author) is an obvious platitude, but to many youthful students of algebra it must be a revelation. At all events, Mr. Clapham's method is wonderfully clear and simple, and to most people it will certainly be novel.

The chapter on Logarithms is very clear, but there is not much room here for any novelty of treatment.

Mensuration is treated at considerable length, and this is the only part of the book really devoted to purely engineering subjects. The chapter on "Graphs" also is mainly engineering, but the instructions in diagram making, and on the uses of squared paper, appeal to others besides engineering draughtsmen.

The final chapter, on the "Slide Rule," is excellent. It contains just the information required by a student who has to rely on private study, and the clear detailed instructions for the practical manipulation of the rule are enough to enable any intelligent person to use one without further help.

Cotton and other Vegetable Fibres: their Production and Utilisation. By Ernest Goulding, D.Sc., F.I.C. London: John Murray. 6s. net.

Among the many lessons which have been taught us by the war, few have been more important than the necessity of drawing the raw materials for our

textile industries to a larger extent than was the case before 1914 from countries within the Empire. The question of increasing our sources of supply will, no doubt, receive attention when the various problems of reconstruction come to be considered; and it is in view of this that Dr. Goulding has prepared the present volume, which gives in a very handy form a summary of the position and prospects of the world's production and utilisation of fibres. The volume, it should be mentioned, forms one of the Imperial Institute series of Handbooks to the Commercial Resources of the Tropics.

The lion's share of the book is naturally devoted to cotton, the raw material of the greatest manufacturing industry in the British Isles. According to the Census of Production of 1907, the total value of the cotton yarn produced in that year amounted to some £96,000,000, and that of cotton piece goods to about £82,000,000, while the number of persons directly employed in the industry was returned as 572,869.

Dr. Goulding gives an excellent description of the cotton plant and its products, the structure of its fibre, the methods of its cultivation and of its preparation for the market. He also deals with the production of cotton in the principal countries and the chief commercial varieties, while a further chapter is devoted to cotton-growing in British West Africa, and other parts of the British Empire. In this connection it is interesting to note that the quantity grown in Uganda rose from 21,566 lb. in 1904 to 13,126,587 lb. in 1914, while that grown in Nyasaland similarly rose from 692 lb. in 1902 to 3,065,248 lb. in 1915.

The other fibres described are flax, hemp, ramie, jute and kindred fibres, and various cordage fibres, while the last chapter treats of a number of miscellaneous fibres, such as pineapple, coir, piassava, kitool, raffia, etc. The book is illustrated by twenty very good photographs.

THE YEAR-BOOK OF THE UNIVERSITIES OF THE EMPIRE, 1916 AND 1917. Herbert Jenkins, Ltd. 7*s*. 6*d*. net.

The compilation of this year-book is one of the outcomes of the Congress of the Universities of the Empire, which was held in London in 1912. It contains, separately for each university, lists of the professors, lecturers, and other members of the staffs, information concerning conditions of entrance, length of terms, courses of study, scholarships, residential facilities, etc., and a summary of events for the preceding year. The universities dealt with are no fewer than fifty-three, and the year-book contains an immense amount of information set forth in a clear and concise manner. It gives rather fuller particulars concerning the universities dealt with than *Minerva*, admirable though that publication used to be, and it will certainly be more gratifying to the Briton in search of information concerning the universities of South Africa to find what he wants under the heading "Cape of Good Hope" than to turn up "Cape Town" and find himself referred to "Kapstadt."

GENERAL NOTES.

STATE INDUSTRIES, BANGANAPALLE.—Mr. M. H. P. Ghatalah has sent to the Society a counterpane woven at the State Weaving and Dyeing Factory of Banganapalle, Madras Presidency, where he is Superintendent of Industries. The factory has been started recently with the object of finding work for the illiterate unemployed. Such men were entertained and trained in the arts of weaving and dyeing. During the period of their training they received a small percentage more than they actually earned by the work they turned out, and now many of them are self-supporting. A "home industry" has also been introduced by lending looms to widows and "Gosha" women, *i.e.* Mohammedan women who are not allowed by their customs to move about in public. Such women were, in many cases, left in a most helpless condition; but they are now engaged in a healthy occupation, and are saved from much privation and misery. Yarn is issued to them, and the carpets which they weave are received into the factory after the women have received a fixed wage for the work done. In addition to this, sericulture and lac cultivation are also being conducted under State supervision.

OVERSEA TRADE AFTER THE WAR.—H.M. Trade Commissioner in South Africa, Mr. U. G. Wickham, in his report for 1915-1916 advises all who intend to interest themselves in that market, when munitions are no longer wanted, to make up their minds that the time for action is *now*. "No doubt they are not, and will not for a while longer, be able to deliver their goods, or even to show catalogues and prices. There is, however, very much that they can do and ought to do." He points out that people at a distance have difficulty in obtaining information as to what is being made for war purposes which has a permanent value as a commercial requisite for civilian use after the war; as to what British manufacturers have learnt to make since the outbreak of war and as to what they can make, are making, or intend to make of the many things wanted in South Africa and at present unobtainable, or being procured from foreign sources. He recently issued a series of circulars broadcast to importers in South Africa inviting advice and criticism, and he says: "I do not care to estimate the number of replies which—with or without concrete instances of past conservatism—reiterate the message, 'Tell the British manufacturer to make what we ask for, and not what he thinks we ought to ask for; tell him that if he does not do so, sentiment or no sentiment, we shall do as we did before, and buy elsewhere.'"

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,397. VOL. LXVI.

FRIDAY, DECEMBER 28, 1917.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 2nd, 3 p.m. (Juvenile Lecture.) P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage."

The lecture will be fully illustrated with lantern-slides.

Special tickets are required for the Juvenile Lectures, and no person can be admitted without one. A few tickets are still left, and these will be issued to Fellows who apply for them at once.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, December 13th, 1917; THE RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, in the chair.

THE CHAIRMAN (Lord Islington), in opening the meeting, said India's trade relations with other parts of the world had been rudely shaken and interrupted by the great world conflict, and it was very appropriate that before the termination of the war careful consideration should be given to the methods by which in future those relations might be renewed, strengthened and improved. The future would demand organisation based on forethought and knowledge to a very much greater extent than had hitherto been the case. With the diversion of trade that must inevitably take place as a result of the war, new openings would arise and new channels would have to be found. Mr. Chadwick would deal in his paper with three countries—Russia, France, and Italy—from first-hand knowledge obtained on the spot. The war had emphasised to a singular degree the importance of tropical produce in the world's economy. A very large and general demand for those products was expected to arise immediately on the termination of hostilities. It would be well known to all those present that India had played a very large and immensely important part in meeting the needs of the Allies with regard to a great many essentials, such as jute, oil seeds, hides, and wheat. It must be fully realised that the competition that prevailed before the war would in no way be abated when the ordinary conditions of interchange of trade once more revived. In the past India's position as a trading country had been pre-eminent, and with energy, scientific organisation and foresight there was no reason why in the future she should not continue to hold that position in the great rivalry that would ensue in the days to come. Mr. Chadwick formed part of a mission that was appointed by the Government of India, to study trade conditions with Russia, France and Italy. The mission received a very hearty welcome in all the countries it visited, and indeed it went to some of those countries in response to a cordial invitation from business men in the chief cities. These invitations, he thought, showed a desire on the part of our Allies to develop trade with the British Empire, and especially with India, a desire to which a most energetic response should be given. They also showed that merchants actually engaged in Indian trade, who, when circumstances permitted, visited those countries, did so definitely to establish trade between them. He hoped that the precedent established by the mission would undergo considerable extension, and that a wide interchange on the part of business men in the respective countries would take place, with a view to developing various branches of trade. Since Mr. Chadwick's return from Italy he had been appointed, under the Government of India, as Indian Trade Commissioner in London. Undoubtedly the duties of that post were going to be of the very first importance in the immediate future,

because they comprised the establishing and organising in the City of an Indian Trade and Commercial Bureau. The staff and equipment were in a state of well-matured development, and he confidently anticipated that the Bureau would render a very great service to traders in this country, to traders in India, and to those who were engaged in the production of various raw materials throughout that great Empire. He would like to make a plea that Mr. Chadwick should receive—as he was sure he would receive—the most cordial support and assistance from all in this country connected with businesses and products in India. However well endowed Mr. Chadwick might be himself — his career in India had been most useful and energetic—his work would avail but little if he did not receive that co-operation. In the task to which Mr. Chadwick had to address himself he would find other sources of assistance of the very first value in bringing him into contact with groups of trading firms interested in the raw materials which were the foundations of their industries, and he would especially commend to his favourable attention, as a great adjunct to his work in the future, the help that could be rendered to him by the Imperial Institute. From the various trade committees, Indian committees, and committees of business men that assembled in the Imperial Institute, Mr. Chadwick could obtain first-hand and up-to-date information with regard to the intrinsic merits of the various raw products used for commercial purposes, and he would find the Institute and its staff ready and willing to render him very valuable assistance. With regard to the three countries with which the paper dealt—Russia, France, and Italy—although one of those countries was now under the shadow of a great ordeal, it might be confidently hoped that, when anarchy had made way once more for law and order, Russia and its people would form a great centre of trading industry, with which, he trusted, India and other parts of the Empire would come into the closest contact at no very distant date. With respect to France, its trade with India was an old-established one of the greatest value, and the fact that the British Empire and France had fought side by side for the past three and a half years to maintain the great principles that underlay the objective of this war would be a great incentive to the furtherance of peaceful relations with France, and the same might be said of Italy. He hoped that after the war the trade policy of the British Empire would be free from all vindictiveness in any part of the world, and that it would be characterised by a broad-minded tolerance even to those hitherto our enemies. He believed that that tolerance could, with ordinary prudence, common sense and foresight, be consistent with ensuring conditions of Imperial security. The British Empire to-day abounded to an almost unparalleled degree in all the raw products that were the basis of the great industries of the world, and some of those raw materials were necessary for the manufacture of articles upon which the safety of the Empire depended. Speaking in no vindictive spirit but in a tolerant spirit of common sense, he ventured to say that the Empire must organise its system of trade in the future, so as to ensure that its raw materials are manufactured within the Empire and not in enemy countries. Therein lay our power as a great Empire. It was an incalculable power if only we made use of it, and he ventured to say that we must make use of it. Our Imperial raw materials must no longer be the prime instrument—in some cases the exclusive instrument—of German trade and industry, but must form the basis, first and foremost, of our own industries, whether those industries were established at home, in our Dominions, in our Colonies, or in India. He hoped that as time went on those industries would be established firmly and would flourish in all parts of the British Empire.

The chair was then vacated by LORD ISLINGTON, who had to attend a Cabinet Committee meeting, and was taken for the remainder of the proceedings by SIR CHARLES C. MCLEOD.

The paper read was—

THE TRADE OF INDIA WITH RUSSIA, FRANCE, AND ITALY.

By D. T. CHADWICK, I.C.S.,
Indian Trade Commissioner.

It is usually considered to be a mistake to begin with an explanation; but I feel that an explanation for distributing sets of tables is due from me. When endeavouring to present a picture of the course of trade between two countries, it is impossible to avoid statistics altogether; and statistics are the bane of a paper. Therefore, the Secretary has kindly distributed them, so that the authorities on which are based many of the statements I shall make can be readily seen, and also that mere figures may be cut out of this paper as much as possible. The tables are taken from the official publications of the different countries, or are directly based upon them. It is not safe to press too closely comparisons between these returns, because the method of compilation and classification varies somewhat between different countries. Bearing this in mind, I would ask, before dealing directly with the trade of India with Russia, France, and Italy, to refer to a few large features of Indian trade—commonplaces probably to many in this room—which are worth restating from time to time, especially in England.

The growth of India's total foreign trade has been especially rapid since the beginning of this century, and exports of merchandise have always exceeded imports. India, judged by the total

value of its foreign trade, stands high among the countries of the world. It is only surpassed by five countries in Europe, and outside Europe by the United States (Table I.). But the course of its trade differs very considerably from that of the other large outlying parts of the British Empire. It would appear from the figures in the *Statesman's Year Book*, that just before the war India obtained from the United Kingdom almost two-thirds of her total imports, whilst the large Colonies got from this country somewhat over a half or a fifth of their requirements. But when one comes to exports from various parts of the Empire, the position is entirely reversed. India finds a market in England for less than a quarter of her exports, whilst Canada, Australasia and South Africa succeed in selling here from half to 90 per cent. of their exports. In other words, whilst India's purchases are mostly made inside the Empire, her sales are mostly made outside the Empire. The importance, therefore, of foreign markets to India's trade is clear, and consequently the importance of these foreign markets to England's sales to India, because imports are paid for by exports.

During these last three years of war a larger proportion has naturally been sent to the United Kingdom, but foreign Continental markets still remain of very great interest to India.

Although the Asiatic markets are very important to India, the European ones are the most valuable. In 1913 foreign countries in Europe took one third of all India's exported goods, and the United Kingdom one quarter; and, curiously enough, India's trade with European foreign countries was practically equally divided between enemy countries and the Allies. Thus, although the channels through which trade will flow after the war are still most obscure, India is obviously very directly interested in the commercial needs and possibilities of the Allies, and, in cases where they have been buying Indian produce through Germany or Austria, in seeing whether direct relations could not be substituted for enemy intervention.

It happened that Mr. Black, who has recently been appointed general manager of the Alliance Bank of Simla, and I were sent on this inquiry first to Russia and then to France and Italy. Conditions, of course, differed widely With France, India had a long-established connection, and a steady trade of about £12 millions a year. With Italy trade before the war had been rapidly developing. With Russia, so far as was generally known in India, trade had on the whole been stationary, and could practically be summed up in the one word "tea." It was impossible, of course, after two years of war, to collect samples of what actually might be required in peace time in the different countries. As one man in Russia said: "In these days, to the man who wants a cat, a black cat is as good as a white one." Of which, probably, the English counterpart is, that the lady who requires sugar does not complain whether loaf or brown sugar is offered. Reliance had thus to be made chiefly on personal interviews with manufacturers and merchants. In all our visits we everywhere received the ready help of our Consuls and British Chambers of Commerce, though the former were often much overburdened with other work. A few had not been in close touch with dealers in raw produce. This was natural; no inquiries had ever hitherto been made to them about these articles, nor had their attention been drawn to Indian trade. In Italy, the Credito Italiano, one of the largest Italian banks, took the greatest interest in our visit, and much trouble and pains to make it useful and profitable. If to-day attention disproportionate to the volume of trade seems to be directed to Italy, it is because Germany had obtained much greater hold there than in France, and because business relations between France and India are older, better established, and stronger than between India and Italy.

Russia.—The main points in regard to Russia can be quickly stated. It is just a year since we were there—*i.e.* before the Revolution. It is difficult to know how far in the meantime internal disorder has damaged the economic future of the country; the time may be long before the course of trade can become stable, and political events in the unknown future may encourage or may gravely delay enterprise; but ultimately the economic needs of a population of 180,000,000, increasing by 2,000,000 a year, must reassert themselves. Thus an examination of the course of Indo-Russian trade before the war has not merely academic interest simply because trade with Russia is temporarily paralysed. Both statistics and personal inquiries showed that in the past Germany had supplied about 50 per cent. of Russia's demands for tropical produce. There is thus trade to be done and organised before the old ties with Germany which have been broken can be reforged.

The extent of German penetration in Russia

almost surpasses the imagination of those who have not been there. In the large towns German and Russian were the language of business—French or English was of little use. Until 1890 German was the language of the Lutheran schools in the Balkan Provinces, and till about the same date there was a German university at Dorpat. Over 10 per cent. of the ordinary commercial and news journals published in Russia before the war were printed in German. We were given to understand that German was obligatory in the commercial schools of Russia. Even British trading houses had in the past given sole agencies for Northern Europe to Hamburg firms. Several Russian banks were organised or developed by German interests; large and compact properties in the towns were owned by Germans; behind all there was a very well-equipped Consular service which Germans used freely. There is no doubt they studied the market and the methods of the Russian. In the process they did not always make themselves loved. As one bank director put it: "The Germans certainly gave you the articles you wanted, but there always came a time when the German tried to do business with his feet on your table."

All this means is, that the Germans were in the towns of Russia. British capital and energy in Russia were mostly directed towards developing the more remote resources of the country, *e.g.* oilfields near the Caspian or mines in Siberia. The development of the natural resources of the remote corners of the world has an irresistible attraction for the spirit of British enterprise and adventure. But it is the men in the towns who are in closest touch with the business life of a country, with its commercial needs and methods, and with its general, financial, and industrial development. It is thus not surprising that Germany quietly gathered to herself as large a share of the trade in tropical produce as that which she had in the trade in manufactured articles India had made little or no sustained effort to develop organised direct connections. British merchants had done something in particular lines, but were completely outnumbered by Germans, and at times employed Germans as their agents.

In thinking of German trade with Russia it is wrong to think of it as confined to trade in manufactured goods.

The Indian statistics give particulars of the goods consigned to a country, and, as far as India knew, Indian trade with Russia outside tea was almost negligible, being only worth about £400,000 a year. Including the tea trade, which had largely been developed by Russian merchants in Calcutta, the total of consignments direct from India to Russia was about £1⅜ millions a year. The Russian returns, however, show that before the war goods known to be of Indian origin to the value of £3⅔ millions reached Russia, and if an estimate be added for those whose identity of origin was lost in transit, due to rehandling or regrading, or polishing, etc., Russia's imports of Indian goods were worth between five and six millions, and covered a variety of articles, although in India we deemed the trade a small one, and one mostly restricted to tea. The figures on which this statement is based, and also the line of argument which shows that this middleman's trade was mostly done by Germany, are given in the tables circulated. It will also be seen that before the war Russia's general import trade was growing rapidly, and especially marked was the growth of her needs for Indian produce. Thus, in spite of the old political mistrust between Russia and India, Indian goods were finding their way into Russia in steadily increasing quantities, and the total volume of this trade was about three times as large as the Indian returns indicated, and for the most part it was done by Germany.

Ample corroboration of the general truth of these statements was obtainable in Russia. Manufacturers and merchants repeatedly told us they had regularly bought Rangoon rice in Hamburg, Indian kips at Leipzig, jute from German houses, and so with pepper, castor, beeswax, etc. One merchant in Moscow went so far as to say, "Yes, you had the goods, but the Germans knew how to sell them"—a sweeping statement which our merchants would certainly not accept, but yet which shows accurately the impression in some business circles in Russia.

Brief mention may be made of the Indian articles in chief demand in Russia. Except perhaps at Warsaw or Lodz, where it can compete with the short-stapled cotton of Trans-Caucasia and Northern Persia, there will be very little demand for Indian cotton. The mills round Moscow use the American variety, and draw most of their supplies from Turkestan, where the crop before the war had reached 1,500,000 bales of American variety. This, by the by, is one of the most successful efforts recently made in the world to extend cotton cultivation in new areas. But this development means a greater demand for jute, which is

required to bale it. Jute was also needed more for general trade purposes, and promised to be in still greater demand. The largest openings seemed to lie with certain foodstuffs, oilseeds, light hides, reagents for soft tannage, medicinal plants, spices, beeswax, lac, and rubber. Russia is always associated in one's mind with tea, which is popular everywhere except in Finland. The consumption, however, is as yet only $1\frac{1}{2}$ lb. a head per annum, as compared, I think, with about 7 lb. in this country. Rice was also advancing largely in favour; but the chief market for Rangoon rice is in North-west and Central Russia. In the south, rice from Persia and Trans-Caucasia, admitted on favourable Customs terms, holds the market. Pepper and spices of all kinds are readily sought for in the towns. In the manufacture of drugs considerable progress has very recently been made, because in the past such manufactures had been stifled by the commercial treaty imposed by Germany on Russia in 1904. This is now void. In oilseeds the position is peculiar. For linseed there is, of course, no need, and for castor an increasing one. But, although Russia is such a large agricultural country, there was a large and growing demand for edible vegetable fats, especially for those made from the better grades of copra. Soap has hitherto been almost exclusively made from tallow. The supply both of this and of the sunflower crop was insufficient for the very rapidly increasing demand for soap. Unfortunately here, however, groundnuts are classified in the Russian tariff as a luxury food, at rates which prohibit their use for industrial purposes. The above are not army demands, but civil ones. Another rapidly increasing civil demand was for long boots with soft uppers—which may also mean reagents for soft tannage such as myrabolams. Even in the villages bast slippers and gaiters were giving way to leather boots; and the towns of Eastern Russia and Western Siberia are very rapidly growing. Several which till recently were villages, have now from 70,000 to 200,000 inhabitants. Lac is in large demand in village industries round Moscow, whilst there is always a big market for scrap rubber for making goloshes, which are widely used by all grades of the community in the towns. The demand for Indian products was thus both varied and growing. Moreover, the articles are not those which cater for luxury trades, susceptible to fickle changes of fashion or to bouts of economy, but consist mainly of staple goods for food, drink or industries, the demand for which, when once established in a town, persists and does not easily disappear.

Last year there was a strong desire in responsible commercial circles in Russia to develop direct trade relations with India on organised and stable lines. Organisation, they said, would be necessary, because trade with Russia could not be built up satisfactorily by correspondence alone. Moreover, competition in Germany's interests would certainly reappear. Further, the largest markets for Indian produce draw their supplies from the Baltic and not from the Black Sea ports, and questions affecting shipping and rates of freight would arise. For instance, we were told that before the war transhipment of goods in Hamburg was much cheaper than at London or Hull, and whilst freights from India to London or Hamburg were nearly the same, freights from London to the Baltic were much higher than from Hamburg to the Baltic. Thus it was much cheaper everyway to ship from India *viâ* Hamburg. It seems also German lines more readily gave through bills of lading to ultimate destination than did British ones. The need for organisation was further emphasised to get to know the actual requirements, methods and changes of the Russian market. British manufacturers in Russia spoke very highly of its stability when once its characteristics were known. Trade connections when once formed were not readily broken. Thus, on account of the need of local knowledge, of the difficulties of the language, of the certainty of questions arising which would affect customs, railways, shipping, and of the probability of German competition reappearing, the greatest stress was laid on joint strong organisation in both India and Russia. Powerful interests in Russia were, and I believe still are, prepared as soon as opportunity permits to co-operate in establishing such joint organisation.

The openings for trade thus promised to be good as soon as political events would permit. It was a market which promised to be both a varied and expanding one, and it was substituting direct trade for one which had hitherto largely passed through German hands. The potentialities still remain.

Russia needs these Indian goods, and will get them. It is surely better to organise that trade direct than leave it to be the foster-child of an enemy country.

France.—The trade from India to France is old established and considerable, viz., about £12 millions a year, and goods in the main go direct between the two countries. Many of

our Indian houses have their own representatives in France, and some of the large French houses have their own branches in India. The general run of our Indian goods is thus well known, and comments turned more on the quality and cleanliness of special articles than on the methods or means of organising trade and commerce. General opinions about the immediate future after the war were for the main part restricted to a wish, frequently expressed, that at least during the period of demobilisation and for some time after, whilst industries are being restarted and stocks replenished, some means would be devised by the Allies jointly to ensure raw materials being directed to Allied countries. No detailed suggestions were made. This was the result of a general appreciation of present actualities; of doubt as to the condition in which Northern France would be found; and of confidence that if only time for recovery was allowed, trade could be restored through the former channels. The self-restraint, patience, and silent determination of France during these three years of trial have won the admiration of the world. Even in the first flush of the news of the German retirement from Noyon, there were no demonstrations or hasty rejoicings. Whilst business men in all towns without exception gave us a very warm welcome, and repeatedly expressed their pleasure that India had sent a small commercial mission to France, the facts of the war were first in their thoughts, and it was not easy to draw from them a detailed forecast of future possibilities. Also the areas which mostly use Indian cotton and linseed were in enemy occupation. A few general features were, however, made clear. As a result of war there has been a large development in the industries of the Rhône Valley, and several of the bigger mills of the north have opened factories here. This will possibly create a new area using some of our Indian goods; and to foster the trade of this tract very large works for extending Marseilles harbour have being pushed on, on which German and Austrian prisoners are being employed.

In new lines of Indian articles there should in all probability be openings hereafter in France for a few articles.

First, hides. Hitherto France has mostly bought Indian skins and has purchased what hides she needed through Germany. The tanning industry has been developed, and is getting into closer touch with the original sources of the raw material. Hides may thus form a new line to France. Jute sacks for Havre, made exactly to specification as to markings and size, may be in demand in spite of the duty, if shipping freights continue high. They are needed for bringing coffee, etc., from Central and South America, and must be exact to description.

In the main, however, it appears that Indian trade with France will follow the former articles with these possible additions, and perhaps tea, which is slowly growing in favour. Indian goods mostly pass into consumption in France, and only a few—*e.g.* pepper and, to a small extent, rice—are re-exported. The scale of import duties has been, and will remain, a large factor in determining the class of Indian goods which enter France. The general effect of these rates appears to be that where supplies from India are not essential for the well-being of a French industry, the goods on entry are subject to duty wherever they compete with products produced in France or in the French colonies. Thus a duty of from 3 to 8 francs per 100 kilos is levied on rice not grown in French colonies, whilst that from Saigon is admitted free. The result is that, except for a few luxury qualities which appeal to a special market, most of the Burmese rice imported into France is re-exported. Over 90 per cent. of that consumed in the country comes from Indo-China. Similarly, pepper not grown in the French colonies pays an extra duty of 104 francs per 100 kilos on entering France. But groundnuts are admitted free, though the best variety on the market comes from French West Africa. The reason apparently is that the supplies from the French colonies are insufficient for the needs of the oil industry in Marseilles, which gets about two-thirds of its supplies of groundnuts from India. More and more attention is being paid in France to the economic development of her tropical colonies, both by improving communications and by testing new crops, and it would seem that in the future India must expect more competition in France from these sources. In view of this possible greater competition in the future the remarks of French dealers on Indian produce are interesting. The manner in which coffee, castor, linseed, rubber, copra, rice, and skins arrived was praised. Other articles were severely condemned, especially hemp, on account of the dust and dirt it contained. Bales of hemp from India and China respectively were opened in our presence and wisps were taken out of the middle and shaken. Less than a minute sufficed to prove ocularly the difference, and the ground of their complaint. Fine dust rose in clouds from the Indian sample, whilst the Chinese one was remarkably clean. Indian

tobacco—*i.e.* the leaf for which there is a market in France—was roundly classed as the worst marketed in the world. If it could be better sorted, approximately graded, and better packed we were assured it would obtain both a wider sale and a better price. Wheat was blamed both for the presence of barley and the frequent mixture of small stones and dust. Consignments have certainly improved in quality but slowly, and whilst Algerian wheat, also grown in the main by small cultivators, was formerly much dirtier, it is now delivered cleaner. Merchants in Marseilles were unanimous in the opinion of a recent fairly steady falling-off in quality of Indian sesamum in recent years. In regard to groundnuts the remarks were partly conflicting. The vast majority said that the machine-shelled nuts were greatly superior to the old hand-shelled ones, which often came damp, wet, and rancid. Others still required the old grade, provided it was not too wet. But these were men who for the most part made the lowest grades of soap, and so required the cheapest article they could procure. The prevailing attitude of the Marseilles market can, however, be best inferred from the action of the dock company. A dock company is not generally supposed to change readily its methods of housing and handling goods; it is usually in a sufficiently strong position, only to move in response to insistent and permanent demands. The practice was to store Coromandel decorticated groundnuts wherever space was available in the docks, either under tarpaulins on the quay or in warehouses. They have now, however, allotted one large dry warehouse for Coromandel dry or machine-shelled nuts, to which these nuts are taken immediately on arrival. This is evidence of a real demand for the better quality, which is also shown by a difference in price for the two articles, both in Marseilles and in India. In fact, this improvement in the handling of groundnuts is probably one of the most successful attempts in India on a large business scale to obtain on the world's market a better price for quality. The ideal machine for decortication has not yet been obtained. Indian shippers may probably be interested to know that on account of the high shipping freights different decorticating machines are being tested in French West Africa, with a view to shipping those nuts also decorticated and not, as hitherto, in shell, which, if they succeed in finding a better machine than we use, means increased competition for our produce. The objection to the machine most used at present in India is that many of the nuts are broken in passing through it. In the old days some of our shipments had been beyond description. The nuts had arrived as a black, putrid, rancid mess which had to be literally hacked out of the hold of the ship. This is, of course, hopeless. The 1912 crop from India had been a very bad one, and though recent ones have been better, the opinion was that there was room for considerable improvement in quality, as our nuts often yielded 4 per cent. less oil than the African ones. In Lyons regrets were expressed over the decay of Indian silk, chiefly because the silk that formerly came from Bengal took a very high polish; it was, for instance, specially prized for the old top hat so beloved of a former generation. The silk manufacturers, however, seemed to despair of any revival of the Indian industry. That which now came forward was so badly reeled and prepared as to be unsuitable for weaving. These strictures did not apply to the silk of Kashmir, which was always well spoken of. Lac was blamed in Paris for its packing. The boxes were irregular in shape, size, and contents, and often not strong, leading to wastage, and loss of time and labour in handling and distribution.

On the whole, though at first after the war there is bound to be a large demand in France for those lines of Indian produce which she was formerly taking—and possibly, in addition, a permanent one, hides, and a more temporary one for jute sacks—it seems doubtful whether the French market will become a more varied one, capable of absorbing articles hitherto sent to Germany. Our manufactured goods, such as jute sacking, tanned skins, and oils have to bear duties, and some of our raw materials which compete with the produce of French colonies do the same. It is a market in which there is likely to be greater competition in the long run, and in which we shall only maintain our position by constant attention to quality, purity, and cleanliness.

Italy.—Italy, after France and Russia, seemed the most buoyant of the three. It certainly seemed the youngest; although among the oldest countries of the world they claim the merits and failings of youth, having that faith, energy and interest in the future which is associated with youth, and feeling acutely and obviously both success and disappointment. It has been no small work to weld together and develop the Italian national sense and national confidence. For, in spite of recent disasters, there is a very marked and distinct national pride and consciousness in Italy. It was largely this realisation

of nationality which drew Italy into the war. For it was the people who forced Italy into the war. The story of how they compelled an almost reluctant Parliament to action is a dramatic one, and can be read in several books. It is well to remember that Italy freed the French frontier in the first days of war, though Bismarck is credited with saying that it was sufficient for him that an Italian corporal with a flag and a drum faced to the west and not to the east. For Italy this is a war of ideals and realities, not one merely to recover the Irridenta, but to end Austrian and German domination under which she has laboured for years. As Mr. Sidney Low says: "Few foreigners before the war knew how far the German financial subjugation of Italy had gone; nor do they see it now in all its significance unless they read such books as those of Preziosi and Henri Hauser, in which the details of this amazing story are given." I must admit that Preziosi's book appears to an Englishman unacquainted with previous conditions as a somewhat violent production. Hauser's book is translated into English under the title "Germany's Commercial Grip of the World." German interests had penetrated in Italy into banking, shipping, industry and trade, and although the Italians admit that they have learnt much from German organisation, etc., a very large number see that their whole economic independence was threatened, and it was not for this that the battles of the sixties were fought, or the hard times which followed lived through. They want to live and let live, and to develop in friendly equality with other nations. In this Britain, through her long and traditional friendship with Italy, possesses both a powerful political and practical advantage. The complaint against the British is that they have too persistently regarded Italy as a land of art, sunshine and scenery, and been blind to her economic and industrial development. I have nothing to do with the political questions, but the interest to India of seeing Italy independent and strong, developing on friendly terms with the British Empire, seems obvious to any one who looks at a map. And the trade between India and Italy in both directions is greater, and seems to possess greater possibilities, than that between Italy and any other part of the Empire.

India's exports to Italy before the war were worth about five millions a year, and consisted almost entirely of raw materials for industries, such as cotton, jute, hides, oilseeds. The only foodstuffs taken in any quantity were wheat and pepper. There is not much scope for introducing new articles of food and drink from India, for Italy grows her own rice, does not drink tea, and prefers the cheaper South American coffee. It is in the development of her industries that the chief market for the future will lie, and the progress made here is remarkable. At the outset, as a manufacturing country, Italy had three great difficulties to contend with—viz., lack of capital, lack of industrial experience, and practically a complete lack of coal and iron. She had, and has, an abundant population. Before the war emigration averaged 680,000 a year, chiefly to the Argentine and America. Where the Italian colonies have settled both in America and the Levant, Italian export trade has developed and grown. In the last twenty years much attention has been paid to banking organisation, and the two largest Italian banks have their own branches in London. There are three large banks, with capital between £2¾ and £6¼ millions. Deposits and current accounts, which in 1912 were £52 millions, were £133 millions at the end of April, 1917. The lack of coal was the most serious material disability, but this has largely been surmounted by the development of hydro-electric installations, which already yield for industry more horse-power than the imports of coal, though the latter were 10,000,000 tons a year. The opportunities for extending the erection of such electric installations are by no means exhausted, and in such development Italy sees a chance of ensuring her own supplies of cheap power. Industrial experience has been obtained in North Italy. The results of all this is, that in the last thirty-five years the value of Italy's imports have trebled, that of her exports have doubled, whilst the trade in fully-manufactured articles had, just before the war, almost attained equilibrium. In passing, it may be noticed that in the same period, in spite of the increased trade and the wider trade relations of Italy, Germany had both, in the import and export trade, risen from sixth to first in importance among Italy's suppliers and markets; and whilst two-thirds of what Germany sold to Italy consisted of fully-manufactured goods, nearly two-thirds of what she bought were articles needed for industry, either raw or partly manufactured. In contrast to this, over half of Britain's sales to Italy were raw materials, mostly coal, whilst nearly half of Britain's purchases were fully manufactured articles—mostly silk. But an industry which

has thus surmounted its earliest difficulties would seem to possess the elements of stability, vitality and promise of progress.

Capital is still needed in the country, schemes for further utilisation of electric power have yet to be carried out; but results already obtained hold out promise for future development. During the war many industries have been able to improve their financial reserves; between the outbreak of war and the end of 1916 new capital up to forty millions had been devoted to industrial companies, and many gaps in Italian industry had been filled. Further, Italian industries have escaped the ravages of war which have fallen so heavily on France, and it is hoped will be, in the main, in running order when peace arrives. Stocks of industrial raw materials are low. Thus after the war an increased and more varied demand for raw materials may reasonably be expected from Italy. Whilst touching on these general features, it is of importance to note that the financial policy followed by the Italian Government in raising its war loans is similar to ours, in that provision has so far been made for meeting new interest charges by increased taxation.

Further, Italy promises to offer an alternative market to some extent to Germany for several of India's products, notably in cotton and hides, and perhaps in oilseeds. The Italian cotton-mills already use a greater proportion—viz., one-fifth of the total raw cotton imported—of Indian cotton than does any of the other large European countries. Their machinery is largely adapted for using lower counts. It is a warm country, and cotton goods are more widely used for clothing than in Northern Europe. Owing to the cost of articles after the war, it is likely that the home demand will turn more to the cheaper class of goods, and in addition Italy will probably continue to supply some of France's needs for such counts until French industry is re-established, since most of the French mills which use Indian cotton are in the invaded tract. Indian hides were bought to some extent in Germany, besides being imported direct. Moreover, a very considerable amount of chrome leather for uppers for boots—for which Indian hides are well suited—were imported from Germany. During the war this process has been developed in Italy, and much attention has been paid to the organisation and development of tanning industries. Before the war about 1,000,000 pairs of boots a year were imported into Italy. Henceforth many of these will probably be made in Italy. Manufacturers laid stress on the acceptance of arbitration at some Mediterranean port, if possible, as a very great assistance to trade. There is scope in hides for a considerable development, and it was a trade notoriously under German control. In oilseeds the position is an interesting one, as it seems to be resolving itself into a struggle against natural economic forces. Castor, which is used for industrial and medicinal purposes, will always be required; but the large future depends on the edible vegetable oils. Italy, with its olives, has been from most ancient times an oil-eating country, and it still prides itself on the quality and purity of its best olive oil. Consequently, in Italy foreign oils and oilseeds are subject to heavy duty on entry. But very largely owing to disease among the trees, production has steadily fallen from 73,000,000 gallons in 1870 to under 40,000,000 in 1913 and 1914. Exports have similarly dwindled from over 20,000,000 to 7,000,000. Meanwhile, the imports of oils and oilseeds have steadily risen in spite of the duty. The local manufacture of soap is also hampered by these duties. Due to lack of labour and attention during these years of war, it is possible that the production of olive oil may still further decline, but it is most improbable that the duties on imported oils and oilseeds will be removed. Most of the growers of olives are small agriculturists in the south of Italy—a class which many say has already suffered by the fiscal policy of the country, and one which looks on this duty as one of the few operating in their interests. Moreover, Government revenue is needed. In spite, however, of the duty and of these vested interests, all things point to more edible oils being needed in the country; and especially whilst freights are high it will probably be preferable to send oil and not oilseeds. The chief competition will be from palm oil, presumably from West Africa, and in cottonseed oil from America. Tanning materials, mica, lac, rubber and gums were also asked for. Indian hemp is required, but once more complaints against quality are to be heard. Coir matting is in use, but appears to have been entirely bought as a manufactured article from Germany. Indian wheat was very largely blamed for the presence of dust, barley grains, and weevils; and although it is well suited for the manufacture of paste and macaroni, the Italians said they only bought it when the Russian and Rumanian crop was short. Latterly, during these years of war, Canadian wheats have been coming to

Italy. Some idea of Italy's needs for wheat can be gathered from the fact that in peace times her total imports are worth about £17 millions, as compared with about £42 millions into the United Kingdom for both wheat and flour. As for jute—jute will always be needed as general trade expands.

Thus there is every probability that there will be a wider field for Indian produce in Italy, and in the past a not inconsiderable share of such trade has been done by non-Empire firms. The Italian market has also improved greatly in general reputation, and deserves to be better known. But German commercial interests were very strong in Italy, and Germany will certainly try to regain some of her position. Care is thus needed in forming connections and appointing agents. Fortunately there are now several strongly-supported organisations, especially the British Italian Corporation, of 3, Lombard Street, with its allied company in Italy definitely working to assist and promote trade relations in both directions between the British Empire and Italy. Italy has surmounted many of her earlier difficulties, and in her industries is showing ingenuity, energy and faith in the future. Trade, too, should be looked for in both directions, for many kinds of Italian goods seem well suited for India's needs, *e.g.* raised cotton goods, electric fans, caps, sulphur, glass, potatoes, coral, etc., and in this trade, and also in outward shipping, German and Austrian houses had a large share. Until trade in goods in both directions more nearly balances, the need for closer co-operation between banks was urged, and better outward services of steamers. In Italian shipping German interests were before the war very strong.

The points I wish to bring out in respect to Italy are—

i. Indian exports to Italy consist almost solely of articles needed in Italy, and are practically all used in Italy.

ii. The volume of the trade from India to Italy depends directly on the welfare of Italian industry.

iii. Before the war Italian industry was in a fair way to surmounting many of its initial difficulties connected with capital and motive power, and was giving proof of vitality and stability.

iv. Italy undoubtedly possesses men—potential workers, potential consumers.

v. The old prejudice against much of the Italian market is said to be out of date.

vi. Germans and Germany exercised before the war much financial and commercial power in Italy.

vii. That, for the time, has gone. This war is for Italy largely a war of emancipation and self-realisation.

viii. Many very strong interests in Italy are desirous of working more closely hereafter with the British Empire on a basis of mutual knowledge, respect, and confidence.

ix. Indian industries are not only in the main intact, but have been extended and financially strengthened during the war.

x. The strain and financial burdens of the war have been very great. This may tend, after the war, to reduce Italy's foreign purchases, but the fall should chiefly be in articles of luxury. India's goods are not mainly articles of luxury.

xi. Italian industry being ready, should find employment quickly, both in replenishing home stocks and in helping to meet demands in neighbouring countries which have suffered in the war. On the whole, it would thus seem probable that the Italian demand for industrial materials will increase and develop.

xii. Trade to be stable should go in both ways. If exchange remains against her Italy should be a cheap country in which to buy.

xiii. There would thus appear to be scope for the development of commercial relations between India and Italy in both ways. Owing to Italy's geographical position it is to the interest of India that such development results through the friendly co-operation of both countries, and without that German intervention which previously existed, especially in the trade from Italy to India.

A few points were general to all the countries we visited. Naturally our system of weights and measures came in for wholesale criticism. Even if we do not change our own system it would help trade to quote in quintals and kilogrammes. Then in most of the countries we visited import duties are high, and are calculated on weight and not on value. A manufacturer does not want to pay duty on dust or other foreign matter. Cleanliness, purity, uniformity and quality are of the very first importance in maintaining and developing our foreign trade. For instance, it is disconcerting to hear Indian hemp and cotton blamed for dust and dirt in England; sesamum seed, wheat and hemp in France; wheat, sesamum and cotton in Italy; beeswax in Russia. It is worse to be told that China sesamum, or Algerian wheat, etc., were originally inferior to Indian, but

are now delivered cleaner. They all agree that deliveries of Indian produce have very much improved of late, but they also agree that in very many articles there is still room for further improvements. The question is an important one for India; it is also a very difficult one.

India has long enjoyed a special position among the tropical producing countries of the world; she still has immense relative advantages in her settled population, her railway system, and her organised foreign trade. But competition from other quarters was coming even before the war—*e.g.* palm kernels from West Africa, copra from the Belgian Congo, cotton from Nigeria or Uganda, wheat from Algeria, sesamum and hemp from China—and though immediately after the war it may be difficult to find capital to build railways, etc., and to open up new areas, yet the big demand that will arise for tropical goods must stimulate production in countries which have already got a start. And the point is that in these countries it frequently happens that either development is under the general direction of a body in very close touch with manufacturing interests, so that care is taken from the start to ensure uniformity and quality in deliveries, or that early legislative action has been taken towards the same end. Competition is bound to come, and it will probably be not only competition in quantity but also in purity, cleanliness and quality. The matter is a very difficult one—no one who has been a director of agriculture can be ignorant of that; but if India is to maintain her high position among the trading countries of the world, these three essentials which affect vitally the methods both of production and marketing require and demand constant attention.

APPENDIX.

TRADE OF INDIA WITH RUSSIA, FRANCE, AND ITALY.

The figures in these tables are taken either direct from the Customs returns of the different countries, or from the *Statesman's Year Book*, or from trade returns of certain foreign towns issued, as a rule, by the chamber of commerce of a town.

I. India's Trade.

(A) *General.* In 1913 the gross value of India's foreign trade was £285,000,000 (excluding treasure and re-export), which placed her seventh among the trading countries of the world. Those with a larger volume of foreign trade were the United Kingdom, Germany, the United States, France, Holland, and Belgium.

(B) *Share of the United Kingdom in trade with India and other parts of the Empire:*—

	Percentage of imports from the United Kingdom to total imports in 1913.	Percentage of exports to the United Kingdom to total exports in 1913.
India	63	23
Canada and Newfoundland . . .	21	46
Australia and New Zealand . . .	55	53
The Union of South Africa	51	92
The rest of the Empire . . .	25	32

(C) *Distribution of India's chief markets (private merchandise only) in* 1913–14. Total value of these exports, £162½ millions (Indian returns):—

To foreign countries in Europe	£56	millions, or roughly	⅓
To the United Kingdom	38	,, ,,	¼
To the rest of the British Empire . .	24½	,, ,,	1/7
To foreign countries in Asia	24½	,, ,,	1/7
To the United States .	14½	,, ,,	1/11
To the rest of the World	5	,, ,,	1/32
	162½		

(D) *Nature of India's sales to Allies and Enemy Countries in* 1913:—Gross totals and articles, in which the value of exports exceeded half a million sterling. Where the value was less than half a million no entry has been made:—

(Figures in thousands of pounds sterling. Indian figures.)

Article	France	Italy	Russia	Germany	Austria-Hungary
Groundnuts .	2,131	—	—	—	—
Jute . . .	2,059	1,138	—	3,569	1,319
Linseed . .	1,214	—	—	568	—
Cotton . .	928	2,121	—	2,811	1,949
Wheat . .	891	—	—	—	—
Rapeseed .	601	—	—	551	—
Hides . . .	—	564	—	1,774	1,241
Tea . . .	—	—	1,110	—	—
Rice . . .	—	—	—	2,530	1,370
Copra . .	—	—	—	636	—
Total value of articles, each of which exceeded half a million	7,824	3,823	1,110	12,539	5,879

(Figures in thousands of pounds sterling. Indian figures.)

Article	France	Italy	Russia	Germany	Austria-Hungary
Gross value of all exports from India in 1913-14 (figures in millions)	11·8	5·3	1·6	17·6	6·7
Total exports to chief Allies in Europe (adding Belgium, £8 millions), £26·7 millions.				Total exports to enemy countries in Europe (adding Turkey, £17 millions), £25 millions.	

Thus the Allies and enemy countries shared about equally in the trade; and the purchases of Germany and Austria-Hungary were more similar to each other than either was to the trade to the Allies, except, perhaps, to that of Italy. They, of course, all competed for jute, and to a less extent for cotton.

II. Russian Trade.

(A) *Russian and Indian returns compared.*

In the Indian Customs returns goods are credited to the countries to which they are consigned; therefore, these returns show the direct sales to a country.

In the Russian returns goods are credited to the country of origin, where this is shown by the documents, and not necessarily to the country of purchase. They thus form some indication of the quantity of Indian goods entering Russia, and known as such, whether they were actually bought from India or not:—

Total value of goods consigned direct from India to Russia in 1913-14 (*i.e.* from the Indian returns)	£1,636,000, of which tea formed £1,110,000
Total value of goods received in Russia, which the documents showed had come from India in 1913 (*i.e.* from the Russian returns) . .	£3,656,000, of which tea formed £1,138,000

The value of the trade was thus at least £2,000,000 more than Indian returns indicated. Most of this was done through Germany.

The Case of Jute in 1912.

In 1912-13 India consigned direct to Russia 175,000 cwt. of raw jute.

In 1912 Russia imported altogether 944,000 cwt., of which she credited 77,000 cwt. to the United Kingdom, 132,000 cwt. to Germany, and 666,000 cwt. to India—or nearly 500,000 cwt. more than the Indian returns showed.

The returns of the United Kingdom show 83,000 cwt. consigned to Russia, which corresponds fairly with the Russian figure for the United Kingdom.

The German returns show 99,000 cwt. to Russia in German "special" trade, and another 425,000 cwt. in the general middleman trade as "jute and other vegetable fibres" to Russia.

The inference that most of that additional 500,000 cwt. credited in the Russian returns to India was bought in Germany seems fair.

(B) *Growth of Russian import trade, according to Russian returns:—*

(Values are in thousands of £ sterling.)

	Average of Years 1898-1902.	Average of Years 1908-12.	1913.
Total value of Russian imports	653	1108	1454
Percentage share therein of	%	%	%
Germany.	33	41·5	47·5
Percentage share therein of United Kingdom . . .	18·7	13·3	12·5
Percentage share therein of India.	1·2	2·2	2·5

As a matter of fact (*vide* above), many of the articles credited to India were actually bought in Germany.

(C) *The share taken by Germany in supplying Russia's needs in a few typical (mostly tropical) raw products in* 1913 (*Russian returns*).

The imports into Russia of the following raw products, cleaned rice, pepper, spices, coffee, tea, jute, copra, castor, hides, skins, tanning materials not ground to powder, beeswax, were worth £13½ millions in 1913, and of this £5 millions are credited to Germany in the Russian returns. Really, Germany had sold more of these articles to Russia than £5 millions, because, even in these articles, Russia credits India with £2¾ millions against India's figure of £1⅓ million. Germany, in fact, did half the total tropical produce trade to Russia.

III. France.

The importance of Indian groundnuts to the Marseilles oil industry:—

(Imports of oilseeds into Marseilles in thousands of tons.)

	1906.	1911.	1914.
Total of all kinds . . .	412	608	528
Imports of decorticated groundnuts (*i.e.* almost entirely from India)	111	201	271
Imports of groundnuts in shell (*i.e.* really from West Africa)	59	106	113
Imports of copra	110	173	98

IV. Italy.

(A) Italy has hitherto always imported more "fully manufactured articles" than she has exported; but before the war a position of equilibrium was being attained. Thus in the seven years from 1907 to 1913 the excess of imports over exports of fully manufactured articles was respectively 13, 15, 11, 8, 4, 4, 2 million pounds.

(B) The growth of Italy's foreign trade, and the rapid advance of Germany therein:—

	Imports into Italy.		
	1878-80	1906-10	1911-13
Value of trade in different periods referred to (that of 1878-80 as 100)	100	252	303
Percentage share therein and position of United Kingdom	% 21 Second	% 17 First	% 15½ Second
Percentage share therein and position of Germany	5 Sixth	17 First	16 First

	Exports from Italy.		
	1878-80	1906-10	1911-13
Value of trade in different periods referred to (that of 1878 as 100)	100	183	213
Percentage share therein and position of United Kingdom	8 Fourth	8 Fifth	10 Third
Percentage share therein and position of Germany	4 Sixth	14 Second	14 First

India has latterly been systematically seventh among importers into Italy (her sales to Italy growing steadily with Italy's increasing trade), and eleventh among the purchasers of Italian goods.

(C) Compares the nature of the Italo-British trade with that of the Italo-German. The figures are the percentages which the country's imports or exports under any class bore to the total import or export trade between that country and Italy in 1913:—

	Imports into Italy.		Exports from Italy.	
	United Kingdom.	Germany.	United Kingdom.	Germany.
Raw materials for industry	58	9	14	21
Materials for industry partly worked	18	23	15	40
Fully manufactured articles	22	66	43	11
Articles of food and drink	2	2	28	28
Total	100	100	100	100

Thus the United Kingdom sold to Italy mostly raw materials (largely coal), and bought mostly fully manufactured articles.

Germany sold to Italy mostly fully-manufactured articles, and bought mostly raw and partially-worked materials.

DISCUSSION.

The Chairman (Sir Charles C. McLeod), in opening the discussion, said it was very fortunate that Mr. Chadwick had been appointed Indian Trade Commissioner, as he possessed not only knowledge on trade matters acquired in India, but also knowledge obtained at first hand in the other countries with which his important paper dealt. He had shown that there was a trade between India and Russia, France, and Italy now in existence; secondly, that this country did not get the full benefit of that trade because most of it went through Germany; and, thirdly, that in order to possess the full benefit we must pay more attention to the quality of the goods produced in India. At the present time little could be done in the way of developing the trade between India and Russia, France, and Italy; but when the war was over it would be possible to increase that trade very largely. Trade could now be done between India and Russia through Vladivostok, and after the war, it was to be hoped, it would be carried on through the Dardanelles Straits. That any part of the trade between India and the three European countries in question should go through Germany was disheartening, and it did not speak very well for the enterprise of the British merchant that he should find the raw material in India and allow the German merchant to obtain the commission on it. For many years he (Sir C. C. McLeod) had been engaged on the problem of trying to secure from India not a better but a cleaner article. The ryot must be taught that if he produced a clean fibre, say, jute, he would get a far higher price for it than if he did not take the trouble to remove the sand and mud and decorticate properly. The same applied to linseed, wheat, and all other raw materials. He did not think there was any country in the world that could produce the variety of raw materials which India was capable of producing, but her trade could not be satisfactorily developed if those raw materials were not delivered in a cleaner state. If the great tracts of land in India were cultivated in anything approaching a scientific manner her trade might be enormous. There were, indeed, great potentialities there, and it was for this country to ensure that everything possible be done for the prosperity of India and her inhabitants.

Sir Charles Armstrong said he had listened to Mr. Chadwick's most instructive paper with very great interest. He was very glad that Mr. Chadwick had been able to undertake his three commercial missions, because it was very important that the position of our trade with foreign markets should be investigated from time to time. He agreed with the statement made in the paper that the most promising of the three countries in question was Italy. For many years Italy had carried on a very large trade with India, and she would continue to buy freely. A difficulty, however, that had been experienced in connection with Italian

trade just before the war was that some of the ports of Italy were not sufficiently developed for a large and increasing business. Steamers would arrive at Genoa and sometimes have to wait there for three or four weeks before their cargo could be discharged, and then the cargo had to be put into boats to wait till the wharves were cleared and it could be taken up the country by rail. That was a great hindrance to trade, and added to the cost of the material. The export trade from Italy to India had been increasing very steadily in the years just before the war, and if after the war German and Austrian goods could be kept out of India—as they deserve to be—Italy could to a very large extent supply the deficiency. He was inclined to think that, during the war, Japan had stepped in and filled the gap to a great extent, because since the war Japan had made considerable strides in all Eastern markets. He agreed with the author that France was not a very promising market. France was a very large buyer of raw material from India, but there was very little trade in the other direction, and he thought that she had so tied herself up with Customs regulations and high import duties, in order to encourage her own industries and those of her Colonies, that international trade had become very difficult. Of the three countries that the author had dealt with, Russia was certainly the most interesting. With regard to Russian competition with British and Indian goods in the Persian markets, in the ten years before the war Russia had made great strides. Before that time Russian goods were confined to the markets of Northern Persia; but during the last ten years before the war they penetrated into Central Persia, and into some of the markets of Southern Persia. Russia, of course, had the advantage of an easy entry into Persia, and it was much more difficult for goods to be brought into the interior of Persia from the south coast, as was the case with British goods. Now that we were in possession of Baghdad, however, our trade to Persia ought to be very much easier; but the best thing to do would be to build the railway that had been proposed from Mohammera, at the head of the Gulf, to Khoremabad. The people of Persia were wealthy, and could afford to pay high prices, and it was certainly a country that we ought not to neglect. With respect to the trade in Indian raw materials which reached Russia *viâ* Europe, the author had stated that Hamburg was a cheaper port than Hull or London, and if that meant that it was cheaper for the Russian buyer to purchase for shipment *viâ* Hamburg instead of *viâ* Hull or London, he was quite right; but as a matter of fact Hull was quite as cheap a port as Hamburg, and, so far as the transhipment trade was concerned, London was only slightly dearer. Hull was really a first-class port and ought to be encouraged; but the difficulty was that freight from India to Hamburg, Hull and London was practically the same. When Indian goods were required by Scandinavian or Russian buyers, those which had come *viâ* Hull or London had to be shipped across the North Sea, which of course added to the cost. Of recent years German bankers had afforded very great assistance to traders in Hamburg, and had given them considerable financial facilities, so that traders in Hamburg could give long credits to their Scandinavian and Russian buyers. They had offered similar facilities to brokers in London, but only on condition that the trade was done *viâ* Hamburg. Germany had also been placed in a more favourable position, owing to the fact that by penetration she had obtained partial control of some of the mills in Russia. In order to bring the trade back to this country, British ships in Indian ports should be placed in a better position than ships belonging to foreign countries. Direct shipments from India might also be encouraged. In connection with oil seeds, the re-export and transit trade of Great Britain amounted to 76,000 tons in 1895, and had dropped to 47,000 tons in 1913; whereas the German export trade from Hamburg had increased from 73,000 tons in 1895 to 250,000 tons in 1913. That showed that whilst our trade was a small one and was declining, the Hamburg trade was a larger one and was steadily increasing.

Sir J. D. Rees, M.P., K.C.I.E., said that everyone in this kingdom, especially those who had money invested in Russia, took an interest in the future of that country, and from inquiries he had made in the City, he found the general opinion was that investments in Russia need not be looked upon with despair. There was a good prospect that in the end the sane elements in Russia would reassert themselves, and that those who had capital invested there would not lose it. The author had spoken of the difficulties of the Russian language, but he thought they were very much exaggerated. They chiefly arose—as in the case of all foreign languages—from the obstinacy and lack of intelligence of those who taught the language and prescribed the course of study. The Russian language was not really a difficult one, and he hoped no commercial or other interest would be affected by its supposed difficulty. He had been very much struck by the remarks the author had made with regard to cotton and tobacco. At the present time there was a committee sitting in India in the hope of inducing the Indian people to pack their cotton and tobacco in a better condition. Owing to the carelessness and slovenliness of Indians in that respect, the Indian trade had been placed at a great disadvantage and had suffered very seriously.

Colonel C. E. Yate, M.P., C.S.I., C.M.G., said that twenty-five years ago, when he was Consul-General at Meshid, in the north-west of Persia, he met General Kuropatkin, who suggested that railways should be built between India and Russia so as to increase the trade between those countries,

but after discussion they found that, owing to the Russian Customs cordon and cost of transit, there were no goods that could then usefully be exchanged. What a change had come in late years! The author had indeed mentioned that the trade in tea had increased between Russia and England, and that that trade had been almost entirely developed by Russian merchants in Calcutta, and had also said that the Indian merchant in Calcutta had done practically nothing to develop direct trade between India and Russia in any way, but the appointment of an Indian Trade Commissioner and the establishment of an Indian Trade Bureau in London showed the progress that was being made, and he believed the prospects of trade with Russia in the future were very good. There was a trade in tea between India and Russia worth £3½ millions alone, and the author had given in the appendix to his paper a list of a dozen different articles for which there was an enormous demand in Russia, worth in 1913 £13½ millions. That trade could no doubt be developed if only the purity, cleanliness and quality of Indian goods could be secured. The Government of India ought to look seriously into that matter and try and secure the cleanliness of the articles sent out of India. Mr. Chadwick had pointed out the importance of this to India, and they looked to the Government of India to take the necessary legislative action in the matter.

MR. J. T. MEADOWS SMITH (Secretary of the British Chamber of Commerce in Paris) said the author had thrown considerable light on the probable trend of commercial relations between India and France in the future. One thing that prevented free traffic between the two countries was the fact that France applied the duties of her maximum tariff to very nearly all Indian products, those duties being, as a rule, 50 per cent. higher than the duties of the minimum, or most-favoured nation, tariff. Certain goods, such as tea, coffee, and spices, could be imported into France from India at the lower rates, but tea and spices from French colonies still had an advantage over those coming from India, as they had to pay no duties at all, as a rule. The fact that most Indian goods had to pay such high duties often prevented their sale in the French markets, and it also operated to the disadvantage of India in another way, because India was not only a great country of production but also a country of transhipment, there being a certain amount of transhipment going on in Calcutta from countries further east. The French rule was that, supposing goods originated in a country enjoying the most-favoured nation treatment, but were, before reaching France, transhipped from a port in a country which did not enjoy that treatment, those goods lost their right to benefit by the most-favoured nation treatment or by the minimum tariff upon their arrival n France. Therefore if goods from China or Japan were transhipped at any British Indian port or in Ceylon, they lost their right to the minimum tariff when they reached France. It would be essential for France, immediately after the war, to receive large quantities of raw materials, many of them being obtainable in India, such as jute, oil seeds, hides, etc., and then India would have the finest opportunity she had ever had for asking the French Government to grant to Indian goods the duties of the minimum tariff. Another thing that hindered trade between India and France was the *surtaxe d'entrepôt*, which all Indian goods coming to France had to pay if they were transhipped at a port not belonging to France. That surtax was usually 36 francs a ton, but in the case of tea it was 600 francs a ton. In the course of his official duties he came into contact with Lyons silk manufacturers, and found that they used comparatively little Indian silk, with the exception of certain classes of *tasar* made from the wild silkworm, and preferred to purchase Japanese and other silks. It might be possible, by working on the lines indicated by the author and constantly aiming at the perfection of Indian products, to make Indian silk as popular in France as the Japanese silks.

On the motion of SIR CHARLES S. BAYLEY, G.C.I.E., K.C.S.I., seconded by Admiral HON. SIR E. R. FREMANTLE, G.C.B., a vote of thanks was accorded to Mr. Chadwick for his paper.

MR. CHADWICK, in reply, said the subject was a large one and it had only been possible to enumerate the chief points which came to notice in their tour. There was not time to elaborate them. He would readily try to explain further if any one wrote. He endeavoured to keep strictly to facts and to avoid expressions of opinion. Sir Charles Armstrong, however, tempted him to mention a general impression which he did obtain. This was but an opinion, and he should be sorry if any one accepted it without careful examination for himself. Directly after the war there was likely to be a very general demand for our Indian products. But, taking a little longer view, Italy, as Sir Charles said, seemed to possess the most possibilities for India of the three countries. In France their products were already well known, and they must expect, sooner or later, more competition from the French colonies. In the far long run Russia, with its immense possibilities and large population, would possibly be the most valuable market of the three, but development would be slower, and organisation was essential for success. It should, however, pay, and therefore not be neglected. In Italy prices might not possibly be so good, but his own impression was that the Italian market was likely to develop most quickly of the three. Also, if goods were required which could not be obtained either in India or in this country, it would very often be worth while to inquire in Italy. That, he gathered, was also Sir Charles's opinion, and he thanked him for expressing it. He also unerringly placed his finger on a weak spot in Italian trade—shipping. He (Mr. Chadwick) heard many complaints in

Italy about differential freights to Genoa. He also heard many complaints about delays at the ports. And he was sure that their Italian friends would agree that quick and efficient handling of goods at ports stimulated trade, whilst the reverse was apt to discourage it. Sir Charles McLeod referred to the need of greater care in the grading and marketing of our produce. This was vastly important, but he would only mention one point in connection with it. It did not matter whether a factory was in Milan, Lancashire, Bombay or Lyons. It needed to be certain of the quality, purity, and cleanliness of the raw material it used. It was not only to the advantage of their reputation in foreign markets that their produce came to hand standardized, uniform, and clean, but to the advantage of their Indian industries, which they expected would develop and extend. The establishment of local industries also reacted on these essentials, because a local industry was often in a better position—if it would—to handle small consignments of better produce than was a large export house. It was, therefore, better able—if it would—to give that slightly enhanced price for quality which was needed to induce producers to pay special attention to these points. The merchant houses had done much in this direction, often at loss and inconvenience, and had repeatedly drawn attention to these points, but the method of their business did not facilitate the ready handling of small lots of better quality. The extension in India of efficiently managed industries ought to lead not only to a better balanced economy, but also to favour the improvement of their grades of produce, and so assist in retaining for India her pre-eminent position among the tropical trading countries of the world. Colonel Yate had commented on the changes time had brought. But they all hoped that they were merely on the threshold of greater economical advances as presaged by the development of their mills, the success of Tata's Iron and Steel Works, the inquiries of the Industrial Commission, the work of the Munitions Board, and the inception and founding of industrial banks. He was greatly indebted to the gentlemen who joined in the discussion for the criticisms and information they had given, and above all for the expressions of their belief in the future—they were more qualified to speak than he was.

Mr. G. Manzi-Fè writes that he is entirely in agreement with what Mr. Chadwick reports in respect of Italy. "I am," he continues, "particularly interested in the question as Managing Director of the British Italian Corporation, whose purpose is to assist financially in the development of trade between Italy and all parts of the British Empire. India has at the present moment our special attention, and we are endeavouring, with our Italian friends, to make such arrangements as we believe best calculated to further the development of Indo-Italian trade."

Mr. A. D. Jackson writes emphasising the necessity for some legislation on the subject of adulteration so far as India is concerned. He adds: "The short-sighted policy of the natives seems likely to handicap them severely in foreign markets in the future as it has done in the past."

PRODUCTION OF SIM-SIM IN EAST AFRICA.

The production of sim-sim or sem-sem (*Sesamum indicum*) seed is an important agricultural industry on the east coast and in the interior lake districts of Africa, writes the United States Consul at Mombasa. The total exportation of this product from the Protectorates of British East Africa and Uganda during the year ended March 31st, 1915 (the latest available detailed statistics), amounted to 27,985 cwt., valued at £21,129, of which amount about 20 per cent. was produced in Uganda, and the remainder on the coastal plain of British East Africa. In that year 28 per cent. of these exports went to India, 22 per cent. to Aden, 18 per cent. to Italy, 15 per cent. to Italian Somaliland, and most of the balance to Zanzibar and France. In former years Germany was the largest purchaser. These figures, it should be understood, do not represent the total production of sim-sim within the territory mentioned, inasmuch as a very large amount is consumed locally.

The sim-sim plant is an annual, growing from 2 to 4 ft. in height, and produces a seed that yields a high percentage of fixed oil. This oil is often used as a substitute for olive oil, and even for oil of almonds. Locally, as well as in India and other countries having a large Indian or Arab population, the oil is used extensively for cooking purposes. The plant thrives in a light, sandy loam soil in very tropical districts. About 16 lb. of seed are used per acre, sown broadcast or in drills 18 in. apart during the months of April and May. It requires about four months for the crop to mature. At the time of harvest the plants are pulled up, gathered into bundles, and left in the field until thoroughly dried. They are then thrashed, and the cleaning is done by hand-winnowing with sieves. An average yield is 180 lb. of clean seed per acre under present native methods, but European settlers who have practised more careful cultivation have obtained double and even treble that quantity per acre.

The Mombasa market price for white sim-sim from Uganda at the beginning of 1917 was 27 rupees (£1 16*s*.) per "gisla" (285 lb.). The yellow seed produced in the lake district of British East Africa sells for about 1 rupee less per "gisla." For export, the seed is packed in bags containing 180 lb.

ENGINEERING NOTES.

Aero-steam Railway Traction.—There is nothing new in steam, or in compressed air, traction. There is, however, a new feature in the combination of these two fluids with compound expansion. We find, says the *Engineer*, in the Proceedings of the French Institution of Civil Engineers, a brief account of aero-steam traction, and a report thereon has been made and a description given by M. Guadon as follows: If firing is stopped on a railway locomotive—or, in certain cases, only continued with drygood coke—and the cylinders are thenceforward supplied with compressed air taken from reservoirs carried on the tender, or from a special compressed-air tender, this "aero-steam" will continue to run the train for a relatively long time without the emission of either smoke or steam, the exhaust vapour from the cylinder being actually condensed into water by the refrigeration which results from the expansion of the compressed air, if this expansion is carried sufficiently far by means of a multiple expansion of the mixed vapour. This is applicable to the following cases, as regards steam locomotion: (1) Tunnels in which the emission of steam or smoke cannot be tolerated; (2) heavy grades on which it is desired to augment speed; (3) metropolitan or suburban lines with frequent train stops, upon which an acceleration of starting speeds is required. Plans are advanced for aero-steam traction in the tunnel about fourteen miles long through the Ural Mountains in Russia.

A New Niagara Falls developing 2,000,000 *h.p.*—Almost everyone remembers the lower Niagara River as running through a narrow gorge which is about 500 ft. wide at the water-line and about 1,000 ft. between the tops of the banks, standing from 300 to 350 ft. above the water, and all realise the naturally great difficulty of a dam in such a location. A glance at Foster's Flats, about 4½ miles below the falls, will show at once how this simplifies the work: more than half of the dam can be built on dry land. This first half will then afford an easy means of diverting the water from the present channel before building the rest of the dam, where the water now flows. There is a 102 ft. drop in the Niagara River from the base of the old falls to Lewiston, with a minimum flow of 220,000 cubic ft. per second. Now, this total head and volume should be developed as a unit in one large dam. The most economical method in developing the river, of course, is to use as much water at the falls as the Governments will allow, afterwards returning the water to the river directly below the falls so that it can be used over again at the proposed new falls made by the dam at Foster's Flats. The masonry structure will be about 1,200 ft. long and 150 ft. high, and it will raise the downstream level of the river about 100 ft. The power-houses would extend downstream from the dam on both the Canadian and American sides, considerable distances being required to accommodate the many turbines necessary. These particulars are from the *Engineering News-Record*.

Rain-making Device.—In the course of his tour of the Trans-Continental Railway, the Minister of Works and Railways, Mr. Watt, inspected the rain-making device set up by Mr. J. G. Balsillie, late Commonwealth Wireless Expert, at Bookaloo, in the vicinity of the Trans-Continental line; and upon the evidence placed before him he has decided that the experiments should be continued. Comparisons made and data collected over some fifteen or sixteen years indicated that Mr. Balsillie's scheme had induced an increased rainfall of between 50 and 70 per cent. in what was known as the Bookaloo area, about fifty miles west of Port Augusta. The Bookaloo apparatus had been shifted to Wynbring for further trials, which would be continued for a considerable period. The Federal Government proposed to obtain two more plants from Mr. Balsillie, and, after consultation with the Government Meteorologist, use one in New South Wales, and possibly one in Victoria, in grazing and wheat-growing areas respectively. The cost of each plant, with a full year's upkeep, was about £800.

Inland Water Transport on the Continent.—In Germany the four chief rivers, Rhine, Elbe, Oder, and Weser, carry four-fifths of the total waterway traffic of Germany. The Rhine carries 43 per cent. In France, the Seine transports 20 per cent. of the total traffic, while the artificial waterways of the north-east of France carry 36 per cent. In Belgium the traffic on the Scheldt forms one-fourth of the whole traffic, and more than half of the total traffic is carried on one-third of the mileage. The intensity of traffic on Continental waterways is much heavier than in England. The average length of travel in Germany is 139 miles, in France 92 miles, in Belgium 13 miles, while in England it is about 17 miles.

The Expansion of Quicklime.—This, when wet, develops an enormous force that acts slowly and almost irresistibly, and has long invited use for mechanical purposes. Successful efforts to utilise this force have been noted in a recent issue of *Rock Products*, which describes its efficient use in breaking up heavy brick masonry. Several 12 ft. by 20 ft. piers, 12 ft. high, were situated between similar foundation piers for engines in operation, and it was necessary to remove them without injuring the machinery. Blasting was therefore inadmissible, and hand-cutting and breaking too slow and expensive. The work was accomplished by drilling 3 in. vertical holes 3 ft. deep and 3 ft. apart in both directions over the entire area of the piers, and filling them within 6 in. of the top with fresh slaked lime, in pieces ½ in. to 1½ in. wide. As soon as the lime was thoroughly wet the tops of the holes were filled

with brick drilling well tamped, and in about ten minutes cracks started in every direction, and the entire top of the foundation pier was broken into 3 ft. cubes.

The Mineral Wealth of Alsace and Lorraine.—M. J. P. Bedson, in his inaugural address to the Manchester Association of Engineers, referred, amongst other matters, to the mineral wealth of Alsace-Lorraine, and pointed out that the invention of Thomas and Gilchrist turned that country into a vast gold mine, by rendering its iron ore useful and valuable. The German ambition is to secure also the great iron basin of Briey, the richest and most extensive of all Europe, estimated to contain from 3 to 4 thousand million tons of ore. Thirty miles away nature has deposited 10,090 million tons of coal in the basin of the Sarre; east of Nancy, partly in France and partly in Lorraine, is one of the largest salt beds in the world; farther east, at Pechslbronn, is an oil district whence 30,000 tons of mineral oil are extracted yearly; and finally, more to the south, near Mulhausen, is a wonderful deposit of potash, rivalling that of Stassfurt.

Assam Oil.—Sir Boverton Redwood, speaking at the general meeting of the Assam Oil Company, said that he attached great importance to the work that had been done during the past year in opening up new territory. For some years they had been hopeful of linking up the two areas which had been productive, and during the past twelve months that work had been proved to a point which entitled them to form the most hopeful anticipations. So confident was he of the deductions which might be drawn from the results obtained that, in his opinion, it had now become essential for the directors to take into consideration an extension of the refining capacity of the company, and a report on that matter had been submitted to the board for their consideration. He added that the results as a whole could not be considered as otherwise than gratifying, and of hopeful augury for the future.

GENERAL NOTES.

Production of Sulphuric Acid in Japan.—H.M. Commercial Attaché at Yokohama (Mr. E. F. Crowe, C.M.G.) reports that the increased export of sulphuric acid from Japan to Russia and China since the beginning of this year has led to steadily advancing prices of this commodity in Japan, and a considerably increased output. Several manufacturers of fertilisers have reduced their output and are devoting their energies to the production of sulphuric acid, while a number of companies have been established for the production of this chemical alone. It is estimated that the rate of production of sulphuric acid in Japan at present is some 582,500 tons per annum. Of this quantity about 421,000 tons are consumed by manufacturers in the production of sulphate of ammonia, hydrochloric acid, etc., leaving some 160,000 tons available for general requirements in the country, which are about 100,000 tons a year. Thus there are about 60,000 tons available for export. It is taken for granted that on the conclusion of the war the export trade will fall off, and it is also probable that there will be a considerable decline in domestic requirements. It is estimated that the output of sulphuric acid in Japan, if continued at the present rate of production, will be some 100,000 tons in excess of the demand on the resumption of normal conditions.

Oil Industry of Trinidad in 1916.—According to the report for 1916 by the Acting Colonial Secretary for Trinidad and Tobago (*Colonial Office Reports, Annual Series*, No. 930), there were ten companies engaged in the production of petroleum in Trinidad at the end of 1916. The total output of oil in that year was 32,475,695 imperial gallons, as compared with 31,666,396 imperial gallons in 1915. Drilling to the extent of 58,390 feet was carried out during the year. Oil was struck in thirty-four of the forty-seven wells drilled. The total number of wells drilled in the Colony up to December 31st last was three hundred and twenty-five. Several refineries have been engaged in the production of petrol, for which there is a large demand locally, as well as in some of the neighbouring islands. Kerosene has also been produced for local consumption. The value of crude petroleum, fuel oil and petrol exported from Trinidad in 1916 was over £200,000, as compared with £79,000 in 1915, thus bringing oil into the third place of importance in the list of exports from the Colony.

Oil from the Bicuhyba Nut.—The Brazilian "bicuhyba" nut, which is found principally in the States of Minas Geraes and Espirito Santo, is understood to have been tested in the United States as an oil-producing nut. The meat is said to contain slightly more than 60 per cent. of fats, and the shells a little more than 4 per cent. The meat of the nut constitutes about three-fifths of its entire weight. Assuming that five-sixths of the oil contained in the meat is extractable, this would mean a yield of about 3 lb. of the saleable product from every 10 lb. of nuts. According to a report by the U.S. Consul-General at Rio de Janeiro, interested persons there who are endeavouring to create a trade in this class of raw products state that the "bicuhyba" nuts are not yet obtainable in sufficient quantities to be exported, and that each tree yields only about 35 lb. of nuts each season. It would not be possible to obtain these nuts at less than £20 per ton f.o.b. Rio de Janeiro, bringing the cost of the extracted oil to about 1½*d.* per lb., without reckoning the high freight rates prevailing.

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes in the City of Westminster.—December 28, 1917.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,398. VOL. LXVI.

FRIDAY, JANUARY 4, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 9th, 3 p.m. (Juvenile Lecture.) P. CHALMERS MITCHELL, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage." (Lecture II.)

The lecture will be fully illustrated with lantern-slides.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

JUVENILE LECTURES.

On Wednesday afternoon, January 2nd, Dr. P. Chalmers Mitchell, F.R.S., Secretary of the Zoological Society of London, delivered the first lecture of his course on "Animal Camouflage." Mr. Alan A. Campbell Swinton, F.R.S., Chairman of the Council, presided.

The lecturer began by observing that in the animal world more brilliant colours and patterns were hidden than were seen. Animals dredged up from the depths of the sea were, in many cases, brilliantly coloured and adorned with intricate patterns. Moreover, colours and patterns were even more conspicuous in the interiors of animals than in their exteriors—as a glimpse at a butcher's shop in pre-war times would show; and in support of the adage that beauty is skin-deep, he suggested that if the chimpanzee and the orang, whose portraits were shown on the screen, were flayed, what remained would be as beautiful as a human being similarly treated.

It was, of course, well known that some animals seem to make themselves as conspicuous as possible, *e.g.* the bird of paradise, or the cock pheasant. A favourite explanation of this is the "wedding-dress" theory, viz., that the bird puts on his gayest clothes when he goes a-courting; but Dr. Chalmers Mitchell inclined to the opinion that, as the hen sits on the eggs and looks after the young, it is important that she should remain as inconspicuous as possible, while the cock endeavours to distract attention from her to himself both by his gay garments and his singing. Other animals, again, like rattlesnakes, try to make themselves conspicuous for different reasons. A snake is a delicate creature, and its ribs, and even its back, are easily broken; and when it is not hunting it lies out in the open, where it will be distinctly seen, and advertises its dangerous presence in the hope that it may not be inadvertently molested.

In most cases animals try to conceal themselves, and one important way of doing so is by endeavouring to match their surroundings. The leaf insect, which is considered good to eat by numerous enemies, is a fine example of this. Another instance shown on the screen was the privet hawk moth. The moth, which flies at night, is dusky, but the caterpillar is bright green, and is hard to see on the leaves of its favourite food.

After describing animals which live in snowy regions, and which have either white coats all the year round, like the polar bear, or summer and winter suits, like arctic foxes, hares, and ermine, the lecturer passed on to spotted and striped animals. Few patterns could be more conspicuous than the spotted coat of the jaguar when seen in a museum or a menagerie; but a remarkable photograph brought out the fact that when in its natural surroundings of forest, the beast becomes almost invisible.

Similarly, even giraffes blend in with their natural surroundings to such an extent that at a little distance it is extremely difficult to detect them.

The lecturer concluded with a remarkable series of photographs, in which it was shown that birds bearing colours and patterns that, out of their natural surroundings, appeared strikingly conspicuous, when in their proper environment almost disappear.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

PROGRESS IN THE METALLURGY OF COPPER.

By H. C. H. Carpenter, M.A., Ph.D., M.Inst.M.M., A.R.S.M.,

Professor of Metallurgy, Imperial College of Science and Technology.

Lecture I.—Delivered December 3rd, 1917.

In the last year of the eighteenth century Great Britain produced about 75 per cent. of the world's output of copper. The Cornish miners supplied most of the ore, and the Swansea smelters extracted the metal. In the United States of America only a few tons were made. In 1913, on the other hand, the positions were reversed. Great Britain smelted and refined barely 6 per cent. of the world's production of this metal, and all but an insignificant fraction of this was derived from imported ores, matte, blister copper, and precipitate or cement copper. In the same year the United States of America furnished more than 55 per cent. of the world's total, and by far the greater part of this was obtained from home supplies of ore.

The purpose of this course of lectures is to give a concise history of this remarkable reversal and, as far as may be, to account for it; to describe briefly the origin and consummation of the Welsh process of copper-smelting and refining which made Swansea so famous for many years as the centre of the world's production; and to present an outline of some of the best modern practice in the U.S.A., now the chief seat of the industry.

I need hardly remind you that, whether in peace or war, copper is, and has long been, second in importance only to iron, not only in the various types of the commercial metal, but also in its numerous alloys. The enormously greater extent to which it is now used as compared with a hundred years ago is, however, not so well known. In 1800 the world's production did not exceed 10,000 tons, and that was probably the high-water mark up to that time; in 1900 it had risen to about 500,000 tons; and in 1912 to about one million tons. Thus, in little over a hundred years production had increased a hundredfold.

It is most probable that copper was the first metal commonly employed by mankind. It has been found in the native condition in various parts of the world, and the natural product required no metallurgical treatment prior to its use. The fact that it was very malleable and could be toughened by very simple mechanical treatment undoubtedly contributed materially to its usefulness in primitive times. The mining and smelting of its ores have been carried on from time immemorial. According to Percy, the Ancients obtained the metal from various localities, among which was the island of Cyprus, where, according to Pliny, it was first discovered. The copper from this island was known in the Roman market as *aes Cyprium*, or Cyprian copper. The adjective "Cyprium" at first used only to express locality, became corrupted into the substantive *cuprum*, which replaced the original name *aes*; and from *cuprum* the English word "copper" is derived.

The Hindoos have smelted copper ores from the very earliest times, and to this day conduct the operation in small blast-furnaces about three feet high. The deposits of Britain are said to have been known to the Phœnicians as far back as 1000 B.C. So far as I am aware, a complete history of copper-smelting in this country has not yet been written, but, in the brief historical survey which I shall attempt, I wish to express my indebtedness to two important and most interesting sources of information. The one is Percy's "Historical Notices on Copper Smelting in Great Britain"; the other Colonel Grant Francis's book, entitled "The Smelting of Copper in the Swansea District of South Wales from the Time of Elizabeth to the Present Day," published in 1867. This book is largely compiled from evidence obtained in the Public Record Office.

A word, however, is necessary by way of introduction with regard to the ore-minerals of copper, more of which exist than of any other metal. Dr. Cullis* gives the following list of fourteen, and this includes only those of major importance:—

* "Mineral Resources of the British Empire with regard to the production of Non-ferrous Industrial Metals," Society of Engineers, 1916.

TABLE I.

ORE-MINERALS OF COPPER.

		Name.	Composition.	Copper per cent.
Native Ores		Native Copper	Cu	100
Oxide Ores		Cuprite	Cu_2O	88·8
		Azurite	$2\,CuCO_3.Cu(OH)_2$	55·2
		Malachite	$CuCO_3.Cu(OH)_2$	57·4
		Chrysocolla	$CuSiO_3.2H_2O$	36·1
		Atacamite	$CuCl_2.3\,Cu(OH)_2$	59·4
		Brochantite	$CuSO_4.3\,Cu(OH)_2$	56·0
Sulphide Ores	Secondary	Enargite*	$3\,Cu_2S.As_2S_5$	48·3
		Tetrahedrite*	$4\,Cu_2S.Sb_2S_3$	52·1
		Covellite	CuS	66·4
		Chalcocite*	Cu_2S	79·8
		Bornite*	Cu_3FeS_3	55·5
	Primary	Chalcopyrite†	$CuFeS_2$	34·5
		Cupriferous Pyrite and Pyrrhotite	Variable.	Variable.

* Perhaps sometimes primary. † Often secondary also.

Of these, cupriferous pyrite and chalcopyrite are the most widely distributed. They are, in fact, the original minerals from which all the others have been derived. The oxide ores are situated in the upper parts of sulphide deposits which have been oxidised under atmospheric influences, and the deposits of native metal are the result of reduction processes operating on solutions of the oxidised ores. There can be little doubt but that the first ores of copper to be smelted were the oxides and the hydrated carbonates. The sulphide ores containing copper, iron, and sulphur in addition to the gangue in which the ore-mineral occurs presented much more difficulty in their treatment and were taken up later. Professor Gowland, however, has described the production of metallic copper from sulphide ores in Japan by a process of superoxidation, and has shown that it dates back many centuries.

Limits of time compel me to restrict my survey of the industry to a period which dates from the close of the sixteenth century. In the time of Queen Elizabeth there was a rich copper mine at Keswick, in Cumberland, where it is reported not less than 4,000 men were employed. This figure is regarded by Percy as a great exaggeration. There can be little doubt but that the ore mined was a sulphide. Webster, the author of the "Metallographia," describes it as an ore "that must be often melted in the fire ere it be brought into the form of good copper." Perhaps I can best illustrate the state of the copper-smelting industry at the works connected with this mine by quoting from a letter from one George Nedham, probably an English smelter, to Sir Francis Walsingham, describing his visit in company with a certain Jochim Ganse, who was a German smelter. The letter runs as follows:—

"A description of the Doeinges of Jochim Ganse and George Nedham at the Copper Mynes by Keswicke, in Cumberland, A.D. 1581.

"RIGHT HONOURABLE,—As soone as Mr. Jochim and I came to Keswicke, the firste thing we did take in hande was to searche out both the nature and the number of the hurtfull humors that were naturally bred in oure Copper ures gotten in that countrie wherein after sundrie trialls we attained to some perfection and found that in our copper ures, were tenn severall substance's whereof iiij ar visible, w'ch ar iron, copper, a kinde of black stone (wherein the copper groweth) and a kinde of white stone named sparr: the other vj humors, w'ch ar in the said ures, and invisible ar sulpher, arsenique, antimony, vitriall, calcater, and allom; so as in ten substances which ar in our Copper ures,

he copper is one, and the other substances by their naturall operation ar all hurtful and venomous humors to the copper; for some of them by wasteinge the copper in smeltinge, and by their dryness make it bretle and black; the other by their toughe and moiste nature, be a great let to the speedie smeltinge and bringinge the ure into rough copper. The number, nature, and propertie of w'ch ix hurtful humors being wholly unknowne to Mr. Daniell and his Sonne, or to any other of the Duch workemen w'ch have bin sente from Germany to the mynes, that have borne our copper ures, had bin the onely cause of the unreasonable charge and long tyme spent before they could make of those ures perfect rough copper: which copper after the order used in tymes past by Mr. Daniell and his son thei never could, nether yet can, make under xxij tymes passing thro' the fire and xxij weekes doeing thereof and sometyme more. But now the nature of these ix hurtful humors abovesaid being discovered and opened by Jochim's way of doeing we can, by his order of workeinge, so correct theim, that parte of theim beinge by nature hurtfull to the copper in wasteinge of it, ar by arte maide freindes, and be not only an encrease to the copper, but further it in smeltinge: and the reste of the other evill humors shalbe so corrected, and their humors so taken from them, that by once roastinge and once smeltinge the ure (w'ch shall be done in the space of three days) the same copper ure shall yeeld us black copper and copper-stone, w'ch nether Mr. Daniell nor his Sonne coulde or yet can do under xvj tymes passinge through the fire and xvj weeks in doeinge thereof: and further, in once rosteinge and once smeltinge the same black copper and copper-stone again, w'ch shall be done in ij days, after Mr. Jochim's order of workeinge, I will bring the black copper and copper stone into perfect rough copper, which Mr. Stembarger cannot make under xxij tymes passing thro' the fire and xxij weekes in doeinge thereof and sometymes more!"

The letter then goes on to describe the part played by the nine impurities in the smelting of copper, and reveals a remarkably shrewd knowledge of their functions. Especially is this the case for iron, as the following quotation shows:—

"The vij[th] humor is Iron, being one of the vij metals but no mynerall w'ch being engendered and bred up in the earth with the copper ure, will not lightlie be gotten from it, and especiallie when the copper ure is smolten greene as it cometh from the myne, w'thout rostinge, then the iron doth joyne and incorporat himself w'th the copper . . . . w'ch is onely the greatest cause of so many chargable fires and longe tyme w'ch Mr. Daniell and his Sonne do spende before thei can make rough copper. And accordinge to Mr. Jochim's order of workeinge the nature and substance of the iron yt is our copper ure being beaten into powder, and rosted as aforesaide, the drosse and corruption that is in the iron is so dryed up that when it cometh to smeltinge it is not able to runne or gether itselfe together like a slagge as it doeth being smolten greene before the ure be rosted: and the best substance w'ch is the right iron ure, beinge by rostinge brought into the perfection of iron, is, by the water and strength of vitriall, converted into copper, as I have proved sundrie tymes: so as this cheefe of the hurtfull humors beinge thus corrected it is made of an enemye a freinde and helper of the copper."

George Nedham, the writer of the foregoing letter, was one of the original partners of the Mines Royal Society, formed in 1580, to which I shall have occasion to allude shortly. The Sir Francis Walsingham to whom he wrote was the secretary of the Society, which had just completed the erection of a copper-smelting works at Neath. I judge from the above letter that the best smelting practice at that period was to be found at the Keswick works, where Daniell (whose surname was probably Hochstetter, and his son-in-law, Stembarger, both of them Germans, were in charge, and that they employed, at any rate, some German workmen. It appears that it took them sixteen weeks to produce "black copper" and "copper stone" (our regulus or matte) from the ore, and another six weeks to convert these into perfect rough copper, and that twenty-two furnace treatments were necessary. The Jochim Ganse was evidently another German smelter who undertook to smelt the ore much more expeditiously, and he and Nedham, apparently acting on behalf of the Mines Royal Society, made the journey to Keswick to carry out the test. That the latter was successful is evident, for, according to the letter, black copper and matte were produced in three days, and another two days sufficed for their conversion into "perfect rough copper," which was the finished product obtained from the smelter. It is evident that, previous to the appearance of Mr. Jochim Ganse at Keswick, it took more than five months to convert the ore into copper, and it is clearly recognised that the chief cause of this very prolonged period was the

presence of iron in the chalcopyrite. On the other hand, after two roastings and two smeltings, Jochim was able to produce the same result in five days' time.

Following on this, Nedham wrote to Walsingham in March, 1582, conveying an offer made by Jochim for "the makeing of copper, vitriall, and coppris, and smeltinge of copper and Lead ures," in which he compared Jochim's charges with those of Stembarger, much to the advantage of the former, and recommended its acceptance. Moreover, it appears from the following extract from this letter that Jochim was to be engaged at the new works at Neath: "And further the said Jochim doubteth not but that after he had rosted and smolten iij or iiij saies of o'r copper ure, in the great works, after such manner as he hath devised since his comeinge from Keswick, to attaine to such farther knowledg of the nature of all o'r copper ures in Cumberland and Westmoreland that he shalbe able to kill all the corrupt humors that be in them, and thereby to bring out more copper than heretofore hath byn."

I have given the above correspondence at some length, not only on account of the interesting picture it gives of the condition of the copper-smelting industry in the year 1581, but because it describes the initiation of what must have been a veritable revolution in ore treatment as a result of Jochim's successful smelting of the Cumberland ores, and because, so far as is known, the smelter alluded to at Neath was the first to be operated in Wales, and may therefore be regarded as the birthplace of the Welsh industry. You will have noticed how closely identified with copper-smelting at that time were German workmen. It is probable that the early ore furnaces of the primitive blast-furnace type in Britain were worked by Germans experienced in that class of work. The matter, however, did not pass without protest. Let me quote from a letter written by Mr. William Carnsewe to Thomas Smyth (January 15th, 1583), who was the "Chief Customer of London to Queen Elizabeth" and the founder of the copper trade in the Swansea district:—

"Mr. Weston's p'vydence in bryngynge hys Dutche myners hether to aplye such busynys in this countrye ys more to be comendyd then his ignorance of o'r countrymen's actyvytyes in such matters, who owte of all p'adventure be as skylfull in mynyge, as harde and dylygent laborers and as good chepe workmen in that kind of travell as are to be founde in Europe; whereof to make you good p'ffe lett the same Mr. Weston's Germans have some myn assignyd only to them, and lett yo'r Ulryke take suche as he is now acquantyd w'th of our countrymen, and the sam that wreoght in that worke at Treworthye laste when it was by Burchardys frowardniss gyvyn ov'r w'che was abowte 23 yerys paste (1560) and let it be consyderyd w'che of them for on hole somers space shall put yow to moste chargys, and gayne yow moste, and soo of them that doo lesse you shall make yo'r estymacyon by p'ffe."

I have not been able to discover whether this test was carried out; it was certainly a fair one.

In the time of Elizabeth, James, etc., the metalliferous ores of this country were reserved to the Crown, and it was necessary to have a grant for the searching for and working of them, and further it was necessary to have a patent or Crown grant for the constitution of a company or aggregation of persons. The Mines Royal Society was constituted in 1580, and obtained its Charter in 1604. There were twenty-four shares, half of which were held by the English and half by foreigners. That the Crown shared in the profits of the undertaking is evident from a note or order on September 6th, 1595, by Lord Burghley that "the Royal Company of Miners should certify what copper they have and how much they owe to the Queen and Customer Smyth's Exors. to answer for copper delivered." The Mines Royal Company lasted for more than two hundred years and conducted operations at Neath. How small the scale of working was even at the end of that time is shown by the following extract from the books of Mr. John Place, their manager:—

"Oct. 10, 1796.—Ores smelted this week 136 tons. Copper made 17 tons; Furnaces working 38; Coals burnt 315 tons."

From this you will see that the weekly output of metal per furnace was less than half a ton, and that the coal consumption was 18·5 tons per ton of copper. The entry of May 16th in the same year is also interesting. "Coal so bad the men left the works for two days." To the Mines Royal Society Wales was indebted for the first copper works established in that country. Nearly one hundred years later two other companies started operations, almost simultaneously, in Glamorganshire. The one was Sir Humphrey Mackworth's "Company of Mine Adventurers," who established works at Melincrethyn about one mile from the town of Neath, where great heaps of copper slag can still be seen. It was also known as the English Copper Company.

Its charter dated from 1691, and it began work in 1695. It appears from entries in the records of this company that it was customary to employ criminals in their mines. Thus: "Sept. 6th, 1700.—An account received that 17 condemned criminals had been pardoned by the King, provided they would within two months, apprentice themselves to Sir H. Mackworth and partners for five years to work at the mines."

"Oct. 16th.—Reported that two of the criminals sent to Neath had run away."

The other company was called "the Governor and Company of Copper Miners in England," and they erected works at Taibach. These were the pioneers of the famous copper-smelting and refining industry of South Wales.

According to Colonel Francis a document in the Muniment room of the Swansea Corporation proves that the first copper works in the Swansea area were erected in 1717. It reads as follows: "In the year 1717 works were first erected upon the river at Swansea for smelting copper and lead ores which works are situated above the town and about two miles beyond the extent of this Corporation. In the year 1720 another work was erected upon Swansea river for smelting of copper ores which is situated within the limites of the Corporation" at Burlaisbrook Junction with Tawe. The dates of the establishment of these and various other works, as given by Colonel Francis, may be tabulated as follows:—

TABLE II.

Place.	Company.	Date.
Neath	The Mines Royal Society.	1584
Melincrethyn	Mine Adventurers	1695
Taibach	Copper Miners	1727
Swansea.	Lane and Pollard	1717–20
Penclawdd	John Vivian	1800
Llanelly	Daniell, Nevill and others	1805
Loughor	Morris and Rees	1809
Hafod	Richard Hussey and John Vivian	1810
Cwmavan	Vigoes and Son	1837
Pembrey	Mason and Elkington	1846

It thus appears that copper-smelting had been extensively carried on at or near Neath for a considerable period before it was established at Swansea, and that it had attained a considerable degree of development there at least 120 years prior to its introduction into the latter town.

I must now pass on to consider briefly why the copper-smelting and refining industry came to be established in South Wales and was able to maintain its position as the greatest producer in the world of the metal from the beginning of the eighteenth to the middle of the nineteenth century. The ores were mined in Cornwall and Anglesey. Why were they brought to South Wales for conversion into the metal? The Cornish pyritic ore was a by-product in the mining of tin, and was originally thrown aside by the miners, under the name of "poder." In the eighteenth century several unsuccessful attempts were made to smelt the ore in Cornwall, of which a record has been preserved by Tonkin. Carew, in his "Survey of Cornwall," first published in 1602, wrote: "Touching metals: Copper is found in sundry places, but with what gain to the searchers I have not been curious to inquire nor they hasty to reveal; for, at one mine of which I took a view the ore was shipped to be refined in Wales either to save cost in fuel, or to conceal the profit." It is clear from the language of the writers of the eighteenth century that the Cornish Mine Adventurers regarded themselves as the victims of a conspiracy on the part of the Welsh copper-smelters, but, as Percy shrewdly remarks: "It is difficult to understand why copper-smelting should have ceased in Cornwall if it had really been profitable. In one instance at least failure was not due either to deficiency of capital or incapacity in the management. As the adventurers felt themselves so much aggrieved by the smelters they might have entered into a combination to keep up the price of copper ore. Of all facts none are more stubborn than those of political economy; and the truth of the matter appears to be that copper-smelting can be conducted with greater profit in Wales than in Cornwall, and therefore it has become extinct in the latter county. . . . It would be difficult to select in this country a more eligible site for copper-smelting works than Swansea, and this for two reasons. The first is that it is a good seaport which is only at a small distance from Cornwall and Devonshire, the two counties in which the greatest amount of copper ore is raised, and it is also easily accessible to vessels conveying ore, or products containing copper, from South America, Australia, and other parts of the world. The second is that

extensive collieries exist in the immediate vicinity from which an abundant supply of coal can be obtained at a low price. Many of the smelters are themselves engaged in the working of collieries, and are thereby enabled to dispose of their coal to the greatest advantage, the large being sold at a good profit, either for home consumption or exportation, and the small, which is often very dirty from an admixture with shale, being reserved for the copper furnaces. It is advantageous both for the mine-adventurers and the smelters that the process of smelting should be carried on in a locality where copper ores of various kinds may be procured, for it is well known that frequently copper can be extracted at a less cost by smelting several ores in admixture than by smelting any one ore by itself."

Few, I imagine, will disagree with the former reason advanced by Percy, but it is not clear to me that the latter had much, if anything, to do with the choice of South Wales for smelting operations in 1584. We must remember that at that time all smelting was carried out in small shaft or blast furnaces, and that charcoal was the fuel used. Coal was not, so far as I know, employed as a fuel in such furnaces. It appears, however, that between 1584 and 1700 the Neath metallurgists had discovered that the free-burning South Wales coal could be used for copper-smelting, and had evolved the reverberatory furnace for that purpose. Indeed, this was a case where the character of the fuel rendered necessary a completely new technique of roasting and smelting. Information with regard to this most interesting change is, unfortunately, I believe, entirely lacking. It is, however, important to note that in his letter of March 1582, Nedham advances as one of the reasons for accepting Jochim's tender, the undertaking of the latter to use nothing but peat in the roasting operations, whereas Stembarger and his father-in-law required to use wood. In the light of this it appears to me not improbable that Jochim and his co-workers would carry out tests on the coal so plentifully abundant in South Wales with a view to adopting it both for roasting and smelting operations. Be that as it may —and whoever made this discovery—once the special adaptability of South Welsh coal for reverberatory firing had been established, and the technique of the new process worked out, smelting practice in this country and on the Continent diverged. In Central Europe, where enormous forests furnished wood suitable for making charcoal, a fuel which necessitates close proximity to the furnace charge, blast-furnace smelting continued to develop and exists to this day, the main difference being that coke has largely replaced charcoal as the fuel. In South Wales, on the other hand, smelting processes developed along the lines of reverberatory practice, and resulted in the establishment of the famous Welsh process. The essential condition for successful reverberatory firing is that the heat must be applied at the right place, and that place is the charge on the hearth—not on the grate or in the flue. What is required is an abundance of incandescent solid particles burning with a more or less opaque yellow or white flame due to incandescence. A very large part of the heat utilised by the charge is received by direct radiation from these particles, and it is this type of combustion to which the free-burning coals of the Swansea coalfield lent themselves in the reverberatory type of furnace.

After reverberatory-furnace smelting had been established there was never any question but that Swansea was a most suitable location for the industry. Fuel was at that time the largest item of expenditure, and remained so throughout the entire period of prosperity of the industry in South Wales. I have already quoted figures showing that at the end of the eighteenth century the consumption of coal per ton of copper produced was 18·5 tons for the mixtures then smelted. This figure had hardly been improved upon at all in 1861, when Percy published his book, for he then estimated that for every ton of copper made from a mixture of ores containing about the same proportion of this metal, 18 tons of coal were still needed. Accordingly a situation where cheap and suitable coal could be obtained was always of the highest importance to this industry. Whether the occurrence of high-class refractory clays suitable for fire-bricks and furnace linings in the immediate neighbourhood of Neath had anything to do with the choice of this place as the original smelting centre is a matter of conjecture. I am inclined to think that it had. At any rate, the existence of the famous Dinas rock in the Vale of Neath was a fortunate circumstance for the copper metallurgists. It found application in the manufacture of furnace bricks and hearth linings, as also did the blown sands on various parts of the coast, some of the best qualities of which are found at Briton Ferry, near Neath.

Preliminary Treatment of the Ores.

The Cornish ores, previous to being smelted in South Wales, were dressed and sampled at the

mine. They consisted chiefly of copper pyrites, intermixed with small quantities of other cupriferous minerals, iron pyrites, and the constituents of the vein in which the ore was found. For convenience of dressing they were divided into three sizes by being dropped on to two rows of inclined bars which separated them into what were termed rocks, roughs and smalls. Each of these then received an appropriate treatment, in which hand-hammering, followed by hand-picking, rolling in a crusher, and jigging, played their part, as a result of which the copper ore was concentrated and yielded two products, the one known as "prills" and "smalls," the other as the "dredge." The former was the richer of the two in copper. These were subdivided into "doles" by means of a measure called a "barrow," which, when filled with ore, weighed about 1·5 cwt. The doles were sampled and assayed by the smelting companies' assayers, and on the basis of their results the various companies fixed the prices they offered at the approaching sale or "ticketing."

It should be remembered that the mining of copper in Cornwall was responsible for the introduction and successful working out of the use of steam power in engineering. "On account of the increasing depth and extension of the Cornish mines, the problem of disposing of the underground water became urgent, and led to the introduction of steam engines for driving the pumps, the Newcomen engine being installed on the Wheal of Fortune Mine in 1720. The success of this engine led to an increase both in depth and in extent of the workings, until it became impossible to cope with the pumping requirements by this means. At the right moment Watt brought out the modern steam engine, and the first Watt engine was erected in 1777 at Chasewater in Cornwall. It was the introduction of these improved methods of pumping which has made possible the successful development of present-day mining. Not only has the steam engine thus led to an increase in the supply of copper by enabling the opening-up of vaster deposits to be undertaken, but the development of engineering science which it has brought about has caused a further consumption of the increasing quantities of copper which it has helped to render available for use."*

The Welsh Process of Copper Smelting.

This process, although now obsolete, was, until comparatively recent times, the most important in the world. It was conducted exclusively in reverberatory furnaces of two kinds—viz., calciners and melting furnaces—and it consisted of at least six distinct operations, but more frequently seven, and sometimes eight, were required. Ores of different kinds and from different localities were generally mixed, so that the mixture contained, on an average, from 8 to 10 per cent. of copper, and was, as nearly as could be, self-fluxing. The fuel was a mixture of binding and free-burning coal burned on a bed of clinker. From time to time modifications of the process have been introduced with a view to omitting certain of the operations and shortening the process. The reactions, however, and the principles on which they depend are essentially the same. The actual problem was the extraction of copper from cupriferous ores in a quartz gangue by the joint agency of air and heat. The following is an outline of the six operations of the smelting process, of which an excellent account is given in Professor Gowland's text-book on "The Metallurgy of the Non-Ferrous Metals":—

1. *Calcination.*—This was carried out in a furnace whose hearth measured from 20 to 30 ft. in length and 10 to 12 ft. in breadth. It was designed to cause a partial elimination of sulphur, so that when the calcined ore was melted a matte consisting of about 34 per cent. of copper, 34 per cent. of iron, and the balance of sulphur and small amounts of impurities, would be obtained.

2. *First Fusion.*—This was called "running for coarse metal," and was conducted in an "ore" furnace on a silicious hearth about 13½ ft. by 9½ ft. With the calcined ore was melted "sharp" slag, from the fourth operation, which contained from 2 to 4 per cent. of copper. The ore charge of about one ton was melted and well stirred, and after being allowed to settle for a time the slag was skimmed off through the front door. Another charge was then added and the operation repeated, and after skimming off the slag, the coarse metal was tapped out through a hole in the side of the furnace. The base of the slag was ferrous silicate, but it also contained silicates of the earthy bases and of alumina. It did not carry, as a rule, more than 0·5 per cent. of copper, present as small globules of coarse metal, and was thrown away. The calcination of the ore produced a certain amount of ferric oxide, which, by reacting with unoxidised ferrous sulphide, produced ferrous oxide. Thus:—

$$3\,Fe_2O_3 + FeS = 7\,FeO + SO_2,$$

* Levy, "Modern Copper Smelting," pp. 5, 6.

and the latter combined with the silica in the charge to form fusible ferrous silicate

$$FeO + SiO_2 = FeSiO_3.$$

Some of the silica also combined with the earthy bases and alumina, and these, dissolving in the ferrous silicate, formed the slag and rendered it more fusible.

The whole of the copper—apart from that carried in the slag—united with the sulphur to form cuprous sulphide, and the balance of sulphur formed ferrous sulphide. These two sulphides dissolved, when molten, to form "coarse metal." The net result of the first two operations was thus to remove the gangue of the ore and to concentrate the copper from about 10 to 34 per cent.

3. "*Calcination*" *of the* "*Coarse Metal.*"—This was ground or granulated and then calcined, sometimes in a reverberatory, sometimes in a Gerstenhöfer, furnace, where the sulphur dioxide could be utilised for the manufacture of sulphuric acid. In this operation further oxidation of copper, iron, and sulphur was brought about.

4. *Second Fusion* (called "running for metal"). —This did not mean metallic copper, but a "regulus" or "matte" of cuprous sulphide. The charge here consisted of about 2·5 tons of calcined coarse metal together with slags from the fifth and sixth operations, both of which were rich in cuprous oxide and cuprous silicate and also with oxidised ores. After melting and skimming of the slag the regulus was tapped out into sand-moulds. Occasionally it was free, or almost free, from iron, and corresponded to "white metal," Cu_2S ($Cu = 80$ per cent.). Usually, however, it contained not more than from 70 to 75 per cent. of copper. If sufficient oxidised ores were unavailable a regulus called "blue metal" resulted, containing from 55 to 60 per cent. of copper, and this required an extra operation. The slag which resulted in this process was called "metal" or "sharp" slag. It was essentially ferrous silicate containing between 2 and 4 per cent. of copper. In this operation the following reactions occurred :—

$$Cu_2O + FeS = Cu_2S + FeO.$$
$$Cu_2SiO_3 + FeS = Cu_2S + FeSiO_3.$$

Silica required for slagging the ferrous oxide was obtained either from the slags and ores, or the furnace hearth.

5. *Roasting to Blister Copper.*—A charge of from 3 to 5 tons of white metal was melted down in a furnace of the same type as that used in operations Nos. 2 and 4, except that it had a port-hole on each side of the fire-bridge and one or more openings in the roof over the fire-bridge for the admission of air. The white metal was piled up in lumps near the fire-bridge, the port-holes were left open, and the firing so regulated that it only melted slowly and trickled down in drops so as to create the conditions for maximum oxidation. When it was melted the slag was skimmed off in order to expose a fresh surface of the matte to oxidation. In this way another layer of slag formed and was, in due course, skimmed off, and these two operations repeated several times. After each skimming the bath was allowed to cool somewhat so that it might "work" or "boil," when sulphur dioxide was expelled vigorously, and the following reactions occurred :—

$$Cu_2S + 3O = Cu_2O + SO_2.$$
$$Cu_2S + 2Cu_2O = 6\,Cu + SO_2.$$

In this way, provided the proper proportion between cuprous sulphide and cuprous oxide was maintained, the whole of the regulus was converted into metallic copper. When the charge was quiet the temperature of the furnace was raised, the slag skimmed off, and the copper tapped into sand-moulds. The complete operation occupied about twenty-four hours, but it depended greatly on the amount of iron and other impurities present. The product was "blister" copper, so called from blisters produced on its upper surface by the escape of sulphur dioxide at the moment of solidification of the metal. The slag was called "roaster" slag, and was essentially a copper iron silicate containing some cuprous oxide and even metallic copper. The percentage of copper in it varied according to the stage of the operation at which it was skimmed. It ran up to no less than about 35 per cent. in the final stages. As mentioned, these slags were sent back to, and treated in, the fourth operation.

6. *Refining.*—The blister copper thus obtained contains a number of impurities. Sulphur, iron, lead, arsenic, and antimony are nearly always present. Selenium, tellurium, zinc, nickel, and cobalt are also liable to occur. Silver is always present and generally gold, and these two metals often occur in quantities that repay extraction. The object of refining—which is also effected in a reverberatory furnace—is to remove these impurities as far as possible and to cast the purified copper into shapes suitable for the manufacture of sheets, tubes, plates, etc., and into ingots for conversion into alloys. At the present day nearly all commercial copper is

refined by a combination of reverberatory furnace and electrolytic treatment, but, for the above purposes, the manufacture of copper refined only in the furnace is still a considerable industry, especially in Wales and the north-west of England. Only the briefest outline of the process can be attempted. In this country the furnaces are of moderate dimensions, the charge being from 20 to 25 tons, since it is found that they lend themselves best to keeping the copper at a "pitch" suitable for castings which have to undergo severe mechanical treatment. The hearth is of ganister or silicious sand, and the sides of the best silica brick. The coal must be free-burning and give a long flame, and it should contain as little sulphur as possible, for copper, when refined, readily absorbs SO_2. The blister pigs are piled up as high as practicable, especially near the fire-bridge, till they fill the furnace from bed to roof. The fire is then made up and the metal rapidly heated until it begins to melt. The port-holes in the roof are then opened and air is allowed to enter freely, the temperature is maintained, and the charge thus melts down and is well oxidised. The bath is then skimmed and freely exposed to the air, and the treatment continued until it contains about 6 per cent. of cuprous oxide. This is aided either by "flapping" or by forcing compressed air either on to the surface of the copper or below it. The test as to when sulphur has been sufficiently expelled is carried out by taking a small quantity known as the "seal," "proof," or "button" sample in a small iron ladle and observing what happens on solidification. If the surface rises, sulphur is still present, and the metal must be further oxidised; if it does not rise about 14 lb. are taken in a large ladle and allowed to freeze. If this rises rabbling is resumed and continued until the large sample not only does not rise on freezing, but actually falls. This is called a "set" and the metal "set-copper." It is then very brittle, owing to the presence of the 6 per cent. of cuprous oxide. After the bath has been skimmed the fracture of a sample is examined, and gives a very good indication of the degree of oxidation which has occurred. It is then reduced by adding anthracite or charcoal and some large logs of green wood, closing up the furnace and filling the fireplace with coal. After some thirty to forty minutes the door is opened and the metal tested for toughness. If the refiner has correctly estimated the number of logs required the copper will generally be nearly tough. A few more logs are then added, and the metal "poled" with a long thick pole of green wood until a test sample freezes in the desired manner. If the surface is depressed and the colour of the fracture brick-red, the copper is "dry," and requires more poling. If, however, it is flat and the fracture salmon-coloured and silky in texture the copper is at "tough pitch." When this is the case an ingot is cast and one end is forged hot down to a thin edge, cooled in water, and the edge turned over and hammered flat. No cracks must be visible. If the tests are satisfactory the metal can then be cast either into copper or iron moulds.

When the crude copper contains arsenic and antimony in quantities exceeding those ordinarily present, caustic soda and lime are added repeatedly towards the end of the rabbling stage, until the so-called yellow metal test gives a satisfactory result. In this case the copper is alloyed with zinc so as to produce the 60 : 40 brass, and this is cast in an iron mould giving a square cake 4 by 4 in., 1 in. thick. This is allowed to cool, is nicked, and then broken under a steam-hammer, and from the type of fracture produced the degree to which the impurities have been eliminated can be judged. The products of the refinery are tough refined copper and refinery slag. The former contains upwards of 99·5 per cent. of copper, and the latter anything from 20 to 50 per cent. of the metal present, either as such or as oxide or silicate. The slag also contains the impurities present in the crude copper, except such as have been volatilised.

A special variety of tough refined copper is that cast for the manufacture of locomotive fire-box plates. These contain from 0·3 to 0·6 per cent. of arsenic. In this case the copper is first refined in the manner just described, and then the arsenic is added, either as metal or as the oxide As_4O_6 mixed with charcoal.

The refining process can be divided into two stages. The first is one of oxidation, in which the impurities, most of which have a stronger affinity for oxygen than copper, are oxidised together with much of the copper. Sulphur is completely oxidised and volatilised as SO_2. The oxidation of arsenic and antimony is never quite complete, and traces of these metals remain in the refined copper. The oxidation of bismuth, selenium and tellenium, is much less complete. Iron is oxidised and passes into the slag. The second stage is one of reduction, and its object is to reduce the cuprous oxide formed in the first stage to the metallic state. However, the reduction must not be complete,

or the metal will be brittle. In spite of the length of time that this process has been worked, and of the number of researches undertaken with the object of determining how the cuprous oxide acts, it cannot be said that a complete explanation is even now forthcoming. The view most generally held is that the oxides of the foreign metals present in the copper are not injurious so long as they remain oxides, and that they are only harmful when reduced to the metallic state, and that the presence of some cuprous oxide tends to keep them in the oxidised condition.

The "direct" process of copper-refining devised by Nichols and James at the Cape Copper Company's works at Briton Ferry, is an ingenious modification of the Welsh process. It was successful in eliminating the operation of roasting white metal to blister copper.

A brief reference to "best selected copper" is necessary. The process by which this variety of copper was made, was devised at Swansea about the beginning of the eighteenth century. Its object was to prepare pure copper from Cornish ores containing tin. To-day it is no longer, or hardly ever, applied to this purpose; but it survives, and is used in the extraction of gold from white metal, and the term "best selected" is still applied to refined copper of special purity. The white metal is roasted so as to produce a partial reduction to copper, and the product is skimmed and tapped out into moulds. There it separates into two layers. The lower consists of metallic copper, and, if the operation has been properly conducted, carries all the gold, part of the silver, nearly all the tin, and much of the arsenic and antimony. These are called "bottoms," and from them recovery of the gold and silver is possible. The upper layer consists of white metal which can be refined in the ordinary way, and yields an unusually pure furnace-refined copper. This is the "best selected" copper of to-day. It may contain up to 99·7 per cent. of the metal.

The foregoing is a brief account of the processes which made South Wales famous for so many years in the history of copper-smelting and refining, and it is no exaggeration to say that they constitute some of the finest examples of skilled metallurgical art with which we are acquainted, especially when the times and working conditions are borne in mind.

In Great Britain the position to-day with regard to copper metallurgy is briefly as follows:—

The actual smelting of copper is a very small industry, and in recent years the few smelters who do exist have found it more and more difficult to obtain smelting materials. The United States of America largely influences the price of copper—I am speaking of the situation before the war—and the policy pursued there is to attract smelting materials from other countries for treatment. The American can afford to pay a high price for imported ores, because the remainder of his raw material is produced at home at a price which is so low that a low average selling price for the whole serves to secure an adequate profit. In the United Kingdom only a few of the large copper manufacturing firms, and one or two companies owning mines abroad, can afford to run smelting works under these conditions.

On the other hand, a large number of manufacturers, not actual smelters of copper from the ore or matte, are engaged in refining Blister, Bessemer, or other varieties of crude metallic copper, and in producing the "tough" and "best selected" brands of the metal. The tough quality is used chiefly by the engineering and shipbuilding industries, and is specified by the Engineering Standards Committee. A variety of this, which is made almost exclusively in this country, is the tough pitch arsenical copper containing about 0·4 per cent. of arsenic. This has a very extended application. The best selected quality is generally made in the form of ingots, and is used for the manufacture of brass and other alloys.

These varieties are for the most part furnace-refined, and I think I am correct in saying that in the production of this class of material our works in this country are pre-eminent. Much the greater part of the copper produced to-day, however, is electrolytically refined. In the United Kingdom the amount of copper treated in this way is very small, and only some half-dozen firms are engaged in this operation. In recent years several firms have discarded their plant, simply because they found that they could not compete commercially with America.

The whole question of the future of the copper-smelting and refining industries in this country is being considered by the Non-ferrous Metal Trades Committee of the Board of Trade, under the chairmanship of Sir Gerard Muntz. It is one of the highest importance. Until this report is published and made available, as I hope it will be, it would be improper to offer any further observation on the situation which exists to-day.

CONDEMNED ARMY BOOTS.

A paper by Mr. M. C. Lamb, in the *Journal of the Society of Chemical Industry*, gives some interesting information about the various methods that have been suggested for making use of the leather in condemned Army boots. Waste boot-leather has been found to be a good road-making material, the scrap leather being mixed in proportions varying from 5 to 10 per cent. with slag, granite or limestone, in conjunction with asphalt and bitumen. This mixture, known as "Broughite," from the name of its patentee, is claimed to possess the hardness and rigidity of a tar macadam road, with less attrition and dust and greater resilience. The method adopted is to lay the surface of the road with the composition, and give a top facing of slag, granite or limestone. One ton of the tarred material is needed to cover six square yards with an application four inches thick, or some 89,000 pairs of discarded boots to each mile of roadway eight yards wide.

"Broughite" appears to be a cheap and satisfactory substitute for wood-paving; it wears better, is equally silent, costs less than wood and no more than bituminous macadam. It affords a good grip for rubber tyres and an excellent foothold for horses. The Roads Board is making trials of its value, and several pieces of roadway have been laid down under its direction.

Waste leather makes an admirable form of animal charcoal. When subjected to destructive distillation, leather yields about a fourth of its weight of a comparatively pure charcoal, which has a decolorising power, as tested on sugar syrups and gelatin, in no wise inferior to bone-char. At the same time, the distillation products afford from 23 to 25 per cent. of crude ammonium sulphate, suitable as a fertiliser.

The leather of boot uppers contains on an average about 15 per cent. of extractable grease and fatty matter, melting at about 38° C., and quite suitable for currying leather, and for other purposes in which a moderately hard low-grade grease suffices. The approximate present value of these products to be obtained from a ton, or 560 pairs, of condemned boots is rather more than £16 11s., of which the charcoal and ammonium sulphate are by far the more important items.

On account of its nitrogen content, leather waste is regarded as possessing considerable potential value as a manure. It, however, decomposes very slowly, and requires special treatment to make it effective. Chrome-tanned material is found to be hurtful to plant-life.

Other uses for condemned military boots are in the manufacture of leather board, leather pulp and powder, clogs, washers for screw-down water-taps, mats, cyanides and prussiates, glue and size.

OBITUARY.

SIR WILLIAM HEERLEIN LINDLEY, M.Inst.C.E.—Sir William Heerlein Lindley, who had been a member of the Royal Society of Arts since 1902, died suddenly at Putney on December 30th, 1917.

Born in 1853, and educated at Blackheath, he began his professional career in 1870, by acting as resident engineer for his father on the waterworks at Budapest. Three years later he became engineer to the city of Frankfurt-on-Main, where for over twenty years he was in charge of all branches of municipal engineering, and of the regulation of the Main. He was also concerned with the electricity supply works at Elberfeld; with sewage works at Elberfeld, Homburg, Mannheim, Wurzburg, Prague, and Cracow; and with water-supply at Warsaw, Bukarest, Cracow, and Baku. At the last-named town he designed and constructed new works, by which water is brought from the Caucasus over a distance of 112 miles.

Sir William Lindley was President of the Engineering Standards Commission of the German Gas and Waterworks Engineers, and of the commission on stray electric currents from tramways. He was knighted in 1911, in recognition of the services which he rendered to the Royal Commission on Canals and Waterways, for which he prepared reports on the waterways of France, Belgium, Germany, and Holland.

GEORGE CLIFFORD WHITWORTH, I.C.S. (retired).—Mr. George Clifford Whitworth died at Grasse, Alpes Maritimes, France, on December 17th, 1917, aged seventy-one. Son of the late Rev. W. Whitworth, incumbent of Little Leigh, Cheshire, he was educated at Sandicroft School, Northwich, and Queen's College, Liverpool, and passed the Indian Civil Service examination in 1867. He served in the Bombay Presidency from 1869 to 1904, the principal posts successively filled by him being Judicial Assistant to the Political Agent in Kathiawar, Acting Secretary to Government, Judicial Commissioner in Sind, Judge and Legal Remembrancer, Additional Member of the Viceroy's Legislative Council (1902), and Judge and Session Judge. He was the author of "The Theory of Relevancy for the Purpose of Judicial Evidence," an "Anglo-Indian Dictionary," and other works. He joined the Society in 1906, and frequently attended the meetings of the Indian Section before he went to reside in the South of France, a few years ago.

GENERAL NOTES.

DISTILLATION OF ESSENTIAL OILS IN INDIA.—Part VIII. of Vol. V. of the official "Indian Forest Records" (Calcutta) contains notes on certain essential oils by the Chemical Adviser to the Forest Research Institute, Dehra Dun. The notes deal with (1) the Eucalyptus Oil Industry in the

Nilgiris; (2) the Distillation of Geranium Oil in the Nilgiris; and (3) the Manufacture of Wintergreen Oil in India. The writer, being impressed with the anomalous fact that, notwithstanding the immense plantations of *Eucalyptus globulus* which exist in the Nilgiris, and the simplicity of the distillation of the essential oil from the leaves, large quantities of this oil should continue to be imported into British India from Australia, proceeded to investigate the question on the spot, and he embodies in his report suggestions for materially reducing the cost of production. An important factor in this reduction is the adoption of a certain form of still, diagrams of which are included in the report. While carrying out experiments in connection with the above-mentioned investigation into the distillation of eucalyptus, the writer also investigated the possibilities of the cultivation of the geranium, which is abundant in the Nilgiris, and the distillation of oil therefrom. He suggests that its distillation could be combined with that of eucalyptus oil without incurring any additional expenditure on outlay, supervision, etc. With regard to the inquiry into the distillation of wintergreen oil (*Methyl salicylate*), the writer concludes that this promises to be a profitable industry in Assam, provided adequate arrangements are made to cultivate the plant. The Nilgiri plant is too poor in oil-content to be considered as a commercial source of *Gaultheria* oil. The above-mentioned publication, which is illustrated by photographs, may be consulted by British firms interested at the Department of Commercial Intelligence, 73, Basinghall Street, London, E.C. 2.

Sugar-cane Wax.—A considerable amount of attention has been given in recent years to the recovery of wax from the waste produced in the extraction of sugar from the sugar-cane, and it is satisfactory to find that this industry has now been started on a small scale in Natal. Samples of the first consignment of Natal sugar-cane wax shipped to this country have been examined at the Imperial Institute, and found to be of good quality, quite equal to that of the first trial samples made and examined. Sugar-cane wax is now becoming better known on the market, and could be used as a substitute for the better known Carnauba wax in the manufacture of gramophone records, polishes, candles, etc.

Increased Printing Charges. — A report received by the London Master Printers from the London Costing Committee states that the total increase in charges for printing since the outbreak of war amounts to 60 per cent., in addition to the increased cost of materials—paper, 200–400 per cent.; ink, 50–200 per cent.; strawboards, 300–400 per cent.; millboards, 150 per cent.; glue, 200 per cent.; cloth, 100 per cent.; and leather, 75–125 per cent.

Fertilisers. — Sir Richard Winfrey, Parliamentary Secretary to the Board of Agriculture, replying to a question in the House of Commons, said: The output of basic slag during the year ending May 31st, 1918, will amount to at least 500,000 tons, as compared with something under 400,000 tons in the preceding season. In addition, certain accumulations of low-grade slag which have not hitherto been regarded as sufficiently valuable to be used will be ground for use if required. The supply of sulphate of ammonia for agricultural purposes is likely to amount to 190,000 tons during the present season, as against 150,000 tons last year. All possible steps were being taken to extend the output.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

January 16. — Reginald S. Clay, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry."

January 23. — Alexander Newlands, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in Great Britain (with special reference to Scotland): its Amount and Economic Value."

January 30.—Sir William George Watson, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." Sir Arthur D. Steel-Maitland, Bt., M.P., will preside.

February 6.—Wm. Frecheville, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

February 13.—Lord Leverhulme, "The Relations between Capital and Labour — Reasonable Hours, Co-partnership, and Efficiency." W. A. Appleton, C.B.E., Secretary of the General Federation of Trade Unions, will preside.

February 20.—Maurice B. Adams, F.R.I.B.A., "Picturesque Architecture." Sir Aston Webb, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

February 27.—Sir William H. Clark, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The Right Hon. Lord Faringdon will preside.

March 6. — A. H. Paterson, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace."

The Right Hon. Frederick Huth Jackson will preside.

March 20. — Frank Stuart Courtney, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." Sir John Snell, M.Inst.C.E., will preside.

Dates to be hereafter announced:—

Major Sir Robert Armstrong Jones, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

George Martineau, C.B., "Sugar from several Points of View."

John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. Lawrence Ball, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

January 17.—H. M. Surtees Tuckwell, M.I.Mech.E., "The Tata Iron and Steel Works." The Right Hon. Lord Sydenham, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., will preside.

February 14. — Sir Henry Ledgard, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India."

March 14.—

April 18.—Alfred Dickinson, M.Inst.C.E., "Water Power in India."

May 30.—Hon. Sir Dinshaw E. Wacha, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

February 5.—C. du Plessis Chiappini, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

March 5.—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

Charles R. Darling, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

Syllabus.

Lecture I.—January 21.—*Methods of Producing High Temperatures.* Special fuel furnaces—Oxy-hydrogen flame—Oxy-acetylene—Thermit—Electric furnaces.

Lecture II.—January 28.—*High Temperature Processes.* Smelting of platinum and metals of high melting-points—Welding and cutting by oxy-acetylene flame and electric arc—Thermit welding—Production of steel and other metals by electric furnaces—Fixation of atmospheric nitrogen—Metal spraying.

Lecture III.—February 4.—*Products and their Uses.* Artificial graphite for various purposes—Carborundum for abrasion and refractory purposes—Alundum and silica for chemical apparatus and refractories—Calcium carbide for making acetylene—Pure metals by thermit processes—Siloxicon and other silicon—Carbon compounds for refractories and thermal insulators—Aloxite and its uses.

Edgar Crammond, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: The Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. Young, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

Cobb Lectures.

Professor Henry R. Procter, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

Juvenile Lecture.

Wednesday afternoon, at 3 p.m.:—

P. Chalmers Mitchell, D.Sc., LL.D., F.R.S., Secretary of the Zoological Society of London, "Animal Camouflage." Lecture II.)

January 9.

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes in the City of Westminster.—January 4, 1918.

No. 3399. JANUARY 11, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society of Arts

CANTOR LECTURES.

A full list of the Cantor Lectures which have been reprinted from the **Journal** and published separately may be obtained on application to

THE SECRETARY, John Street, Adelphi, London, W.C.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. Riall Sankey, R.E., M.Inst.C.E. (1912.) Price 1*s*.

Aeronautics. Three Lectures. By Prof. J. E. Petavel, D.Sc., F.R.S. (1913.) Price 1*s*.

Surface Combustion. Three Lectures. By Prof. William Arthur Bone, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s*.

Motor Fuel. Three Lectures. By Prof. Vivian B. Lewes, F.I.C., F.C.S. (1915.) Price 1*s*.

Coal and its Economic Utilisation. Three Lectures. By Prof. John S. S. Brame. (1917.) Price 1*s*.

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. William George Fearnsides, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s*.

Journal of the Royal Society of Arts.

No. 3,399. VOL. LXVI.

FRIDAY, JANUARY 11, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, JANUARY 16th, at 4.30 p.m. (Ordinary Meeting.) REGINALD S. CLAY, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry." SIR FREDERICK BRIDGE, C.V.O., Mus.Doc., will preside.

THURSDAY, JANUARY 17th, at 4.30 p.m. (Indian Section.) H. M. SURTEES TUCKWELL, M.I.Mech.E., "The Tata Iron and Steel Works." The RIGHT HON. LORD SYDENHAM, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., will preside. The paper will be illustrated by cinematograph views.

Further particulars of the Society's meetings will be found at the end of this number.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

JUVENILE LECTURES.

On Wednesday afternoon, January 9th, Dr. P. Chalmers Mitchell, F.R.S., Secretary of the Zoological Society of London, delivered the second and final lecture of his course on "Animal Camouflage."

The lecturer said that the whole of the animal kingdom was full of patterns of the most startling kind, every part of the body, inside and outside, showing the most complicated and elaborate patterns, but nearly everywhere where the colour could be seen it was camouflaged in some way or other, in order to conceal the animals from their enemies.

It was extremely important for animals to hide their shape as much as they could, and they adopted many different ways of doing that. One of those methods was by very large and grotesque horns, such as the antlers of some kinds of deer. For example, in the case of reindeer on open plains with a background of trees, the branching horns served to hide the usual animal shape, and from a certain distance they blent with the irregular background of branches of trees, etc. The antlers also served to camouflage the animals by altering their shadow. When animals lay down and went to sleep they tried to make themselves look as unlike animals as possible by adopting various attitudes; for instance, some curled up, hiding their legs, others hung downwards from branches of trees, and birds went to sleep with one leg drawn up. A self-coloured animal became very conspicuous when the sun was shining, the upper part of it being brilliantly lit up and the lower part in shadow; and therefore it was very common for animals to be countershaded—dark above and light below in order to camouflage themselves. That method was to be seen in certain eagles, in penguins, wild donkeys, and kangaroos. Another method of camouflage was striping. It was commonly supposed that tigers were striped in order to match the jungle which they inhabited; but, as a matter of fact, tigers did not originally belong to jungles at all, but to open country much further north than the jungles of India and the tropics that they now inhabited, and their striped skin was simply a method of making them invisible by causing them to blend with the background better when seen from a distance. There were many different varieties of pattern and arrangement of the stripes, which Dr. Chalmers Mitchell illustrated by lantern-slides. In some cases the fully-grown animal, being able to protect itself when attacked, was not striped at all, whereas the young animal was. Another method by which animals concealed their shape was by being marked with a

pattern that served to break up the outline of their bodies. For instance, when the skunk was looked at from above it was clearly visible, but when looked at from underneath, in the way that the animal it was preying upon would see it, its shape was broken up by the manner in which it was marked. The lecturer concluded with a number of slides showing that in many cases animals were only camouflaged when young and incapable of protecting themselves.

On the motion of the Chairman, Mr. Alan A. Campbell Swinton, F.R.S., Chairman of the Council, a vote of thanks was accorded to Dr. Chalmers Mitchell for his interesting course.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

PROGRESS IN THE METALLURGY OF COPPER.

By H. C. H. Carpenter, M.A., Ph.D., M.Inst.M.M., A.R.S.M.,
Professor of Metallurgy, Imperial College of Science and Technology.

Lecture II.—Delivered December 10th, 1917.

According to an estimate by Brown and Turnbull* the total copper produced from mines in the United Kingdom in the nineteenth century (1801–1900) was 864,660 long tons, distributed as follows:—

Cornwall and Devon	729,500
Ireland	69,000
Anglesey and other districts	66,160

As regards Cornwall and Devon, the mining of copper dates back certainly to the reign of Queen Elizabeth. It was obtained then—though in very small quantities—from mines at Perran Sands. The district was worked almost continuously from this period until the end of the nineteenth century—*i.e.* for about three hundred years. In most cases each individual mine had only a brief life. The following table† is given as the result of an investigation of the mines of this district for a period of thirty years:—

35	mines	lasted	20 years.
40	,,	,,	10 ,,
31	,,	,,	5 ,,
114	,,	,,	less than five years.

In Ireland mining was carried on throughout the eighteenth and the greater part of the nineteenth century (until 1880). Anglesey produced copper in Roman times. Mines were opened up again in the eighteenth century, and the industry carried on well into the nineteenth century.

The production and price of the metal in decennial periods is given by Brown and Turnbull as follows:—

Period.	Output (tons).	Price (£ per ton).
1801–1810	65,000	160
1811–1820	73,400	130
1821–1830	109,900	101
1831–1840	144,000	94
1841–1850	138,200	88
1851–1860	142,200	111
1861–1870	116,300	87
1871–1880	48,700	79
1881–1890	21,300	60
1891–1900	5,660	55

From this it is clear that the copper-smelting industry based on home ores underwent a great expansion in the period 1821–30; that it reached its zenith in the next decade, and maintained this with slight fluctuations for about thirty years; that between 1861 and 1870 a decline set in which was greatly accentuated in the succeeding decade, and that in the final period the production was less than one-tenth what it had been in the opening decade. Let us briefly examine the history of the industry in these periods. Although, as I have mentioned, the chief seat was in South Wales, ores were also smelted and refined in the Midlands, South Lancashire, and Yorkshire.

The expansion in 1821–30 was due primarily to the use of steam-hauling and pumping machinery in the Cornish mines, which enabled them to be worked to greater depths than before. Even at this time mining at a depth of 1,800 ft. was considered a great achievement. In the next decade foreign ores began to be imported into the United Kingdom, notably from Chile, and in the succeeding decade production began in the United States of America with a yield of 100 tons in the year 1845. Mining operations were begun in South Australia at the Kapunda and Burra-Burra properties, the ores being chiefly oxides. There was also a considerable amount of copper ore mined in Cuba.

* "A Century of Copper," p. 24.

† Hunt's "British Mining," p. 830.

Notwithstanding the great increase in production of this period, the metal was readily absorbed in the engineering and allied industries. In particular, copper and yellow metal were extensively applied to the sheathing of wooden ships. Most of the world's copper was sent to be refined at Swansea during this period; but from this time onwards the British copper-mining industry commenced to decline and Swansea became to a greater and greater extent dependent on foreign sources of ore. It was this development of foreign supplies and the unsatisfactory treatment which the producers received at the hands of the smelters which was the cause of the eventual displacement of Swansea from its position as the chief seat of manufacture.

From 1851 to 1860 was the critical decade. Early in the nineteenth century there was formed the Associated Copper Smelters at Swansea. On the authority of Brown and Turnbull it may be stated that it was designed "on the one hand for the purpose of keeping the prices of copper ore and regulus low; and, on the other hand, of keeping up the selling price of tough and other kinds of copper." This was a very favourable period for its operations, as there was abundance of copper ore to be had cheaply, and a great demand for the metal was growing up in the engineering trade. These large additional sources of supply made the Swansea smelters very independent and difficult to deal with. The *modus operandi* of the Association was to arrange a day in Swansea when the different parcels of ore were put in and ticketed, and these days were called the "Swansea Ticketings." Each smelter bid for the ore he required at his own price. It was supposed that there was a competition going on amongst the smelters, but practically there was none, as they largely agreed among themselves what they would pay for each class of ore and regulus. Chile had by now become the most important producer. In those days the ore was always carried in sailing ships, which, owing to their being wind-propelled, did not arrive with the regularity since accomplished by steamers, and many ships were thus, with a change of wind, brought to port on the same day. The smelters, watching these collective arrivals, regulated their prices for ore in anticipation of the ticketings, and so secured large profits subsequently by raising the "Associated" price for the metal when the operation was completed. In this way they sold, at a high price, the copper which they had obtained at a low price by their combination. The Swansea smelters thus forced the mine-owners to seek a remedy, and this they did by smelting the ore either at or near the mines and exporting the metal instead of the ore. In 1842 Lambert introduced reverberatory furnaces into Chile, and they were so successful that in a short time they were in use throughout the country. In 1857 he erected the first blast furnace there, and the smelting industry then grew so rapidly that, whereas in the period 1856–65 the exports were in the proportion—ore 21·5 per cent., regulus 38 per cent., and bars 40·5 per cent.; in the period 1886–95 they were, ore 1·5 per cent., regulus 3·5 per cent., and bars 95 per cent. The ultimate effect was to widen the market for the finished Chilian product, and Continental purchasers were thus enabled to obtain their supplies of metal direct, instead of being obliged to purchase from the Welsh smelters on the unsatisfactory terms then prevailing. The rise of Chile as a producer of copper is evidenced by the following figures:—

Decade.	Production (tons).
1831–1840	45,000
1841–1850	88,100
1851–1860	214,500
1861–1870	447,400
1871–1880	483,300

In the decade 1861–70 Chile definitely took the lead as the world's greatest producer, contributing about half the total manufactured. This period is also memorable in that it witnessed great developments in mining at Calumet in the Lake Superior District, U.S.A., where the copper occurs native in quantities varying, on an average, from about 1 to 3 per cent. in the ore-body. Percy states that in 1858 no less than 6,000 tons of copper were produced from this district alone. The ore is of three kinds, in each of which, however, the copper occurs native: (1) Vein deposits, consisting of enormous masses of copper; (2) the conglomerate, in which the metal is tolerably evenly distributed, and mostly in a fine state of division in the rock, the latter being very hard; (3) the amygdaloid, in which the metal is highly segregated, and is found replacing other minerals. Some of the copper aggregates in the vein deposits are very large. Percy mentions that in 1854 not fewer than forty men were engaged during twelve months in cutting up a single mass of native copper weighing about 500 tons. Native copper

is generally remarkable for its toughness. A specimen from Chile, about three-eighths of an inch in thickness, is instanced by him as having been bent backwards and forwards forty-eight times before breaking.

The special feature of the next decade was the entry of Spain and Portugal as large producers of the metal from cupreous pyrites. Chile maintained its increased production, and increases came from Australia and the United States of America. The Spanish and Portuguese industry had its origin in the following circumstances described by Mr. Gossage, in a paper read at the British Association in Manchester in 1861. A French trading company in Marseilles persuaded the King of Sicily that his revenue would be improved if he granted them a monopoly of the export of sulphur. The effect of this was that the price advanced from its original figure of £5 to £14 per ton. It was then discovered that our own Cornish mines, and especially those in co. Wicklow, Ireland, constituted an available source of sulphur of great value, and chemists quickly devised methods of converting this into sulphuric acid. The King of Sicily thus conferred a great boon on this country, since his monopoly was destroyed and considerable sums of money were beneficially circulated both in Cornwall and Ireland. The supply in these districts lasted from about 1840 to 1860, but at the end of this period was quite insufficient for the demand. New sources were then found in Andalusia in Spain, and the adjoining districts in Portugal, and in succeeding decades these furnished notable quantities, not only of sulphur, but also copper and iron. The San Domingo and Tharsis Mines were reopened and passed under English management, and in 1876 the Rio Tinto Company of London took over the working of the famous mine of that name from the Spanish Government, and has continued to work it ever since.

This copper or cupreous pyrites is, in most cases, used first of all as a source of sulphur for sulphuric acid in the manufacture of sodium carbonate. In the early days of its use the residues were thrown out as waste. About 1862, however, the Henderson process for extracting the copper by a wet method from the burnt ore was invented and proved successful, and thereafter these residues were sold to copper smelters and had their copper extracted. The residue from this process left the iron in the form of ferric oxide containing a trace of copper, and was known as "purple ore" or "blue billy." This was sold to iron puddlers and was used by them for lining the hearths of their furnaces, and in this way most of the iron was converted into metal. The ore thus became valuable as a source of its three chief constituents—sulphur, copper, and iron. The production of copper from Spanish and Portuguese sources is shown in the following table:—

Decade.	Production (tons).
1841–1850	3,850
1851–1860	24,700
1861–1870	80,900
1871–1880	195,900
1881–1890	482,900
1891–1900	537,300

The treatment of the Rio Tinto ore deserves special mention. It is a massive cupriferous pyrites containing up to 3 per cent. of copper. It is used as a source of copper in the first instance, and it is the best known and, until lately, so far as I know, has been the only large-scale example of the extraction of the metal from its ore by wet methods. The process consists in allowing huge heaps of the mineral to oxidise in the air, in washing out the copper sulphate formed by water, and precipitating the copper from the solution by metallic iron. The fact that this procedure can be, and is, commercially successful is due fundamentally to the fact that the copper exists in a particular state of combination in the ore. When copper occurs as chalcopyrite, $CuFeS_2$, it does not oxidise by mere exposure to the air. In the form of covellite, CuS, oxidation proceeds very slowly. In the case of chalcocite, Cu_2S, however, the oxidation reaches a much higher rate. The bulk of the Rio Tinto ore is chalcocite. When the mineral is exposed freely to air and moisture the following reactions occur.

1. Some iron pyrites are oxidised:—

(*a*) $FeS_2 + 7\,O + H_2O = FeSO_4 + H_2SO_4$.

2. The ferrous sulphate is readily oxidised to ferric sulphate:—

(*b*) $2\,FeSO_4 + H_2SO_4 + O = Fe_2(SO_4)_3 + H_2O$.

3. The double decomposition between the ferric sulphate and the sulphides of copper renders the latter soluble:—

(*c*) $Fe_2(SO_4)_3 + Cu_2S = CuSO_4 + 2\,FeSO_4 + CuS$.

(*d*) $Fe_2(SO_4)_3 + CuS + 3\,O + H_2O = CuSO_4 + 2\,FeSO_4 + H_2SO_4$.

Reaction (*c*) causes half the copper to go into

solution in a few months, whereas it takes about two years to dissolve 80 per cent. of the remaining half of the copper.

The following is an outline of the process, of which a full account is given in the *Transactions* of the American Institute of Mining Engineers, 1904. A site is chosen where the ground is impervious to liquids, and slopes so as to enable the copper liquor to collect and run out at the base of the heap. A network of air flues on the ground, about twelve inches square, made of rough stones is first made and then a number of vertical chimneys, fifty feet apart, are built in the same manner while the heap is being made and are connected with the ground flues. The ore is broken down to lumps of from two to three inches diameter. The coarse and fine products are built into a pile of about thirty feet in height, the upper surface being kept level. The heap contains about 100,000 tons of ore. Its top surface is formed into squares by means of ridges, so that water can be run over it in order to ensure that all parts are equally washed. Oxidation starts rapidly and the temperature in the flues rises to from 77° to 82° C. Care is needed to prevent the heap catching fire. When oxidation has proceeded sufficiently far, water is run on until soluble copper salts have been extracted. Oxidation is then allowed to begin again and the process repeated. After the lapse of a year the surface requires "retilling," and the squares are arranged in different positions. When the copper content is reduced to 0·3 per cent. the process is discontinued. The residue is exported as "washed sulphur ore" and sold to sulphuric acid manufacturers.

The copper liquor, as it runs from the heap, contains some ferric iron in solution, which is removed by passing it over a small heap of fresh ore which reduces ferric to ferrous iron—$7\,Fe_2(SO_4)_3 + FeS_2 + 8\,H_2O = 15\,FeSO_4 + 8\,H_2SO_4$. This reaction is completed in a reservoir formed by a masonry dam across a small ravine, and here the liquor remains until it is drawn off to the precipitating vats. As it enters these it contains about 0·4 per cent. of copper, 0·1 per cent. Fe_2O_3, 2 per cent FeO, 0·03 per cent. arsenic, and about 1 per cent. free sulphuric acid. The liquor is run through long trough-like precipitation vats over pig-iron, which throws down the copper as "cement" or "precipitate." These are arranged on the slope of a hill, and the solution passes backwards and forwards through them until it is discharged free from copper. The vats are of wood, and vary from 200 to 400 feet in length. Some of them are cut out from the series and cleaned daily, and the "cement" is removed and taken to the cleaning and concentrating plant.

Containing, as it does, about 70 per cent. of copper, it is thrown a little at a time on to a perforated copper plate placed at the head of a long launder, and is washed through it by a strong jet of water. The material which does not pass through consists of leaf-copper and small pieces of iron. This is thrown into a heap and sorted to remove the iron. The precipitate which passes into the launder is turned over against the stream of water and concentration effected in this way. It is divided into three grades: "No. 1 precipitate," which collects in the first few yards of the launder, is the purest, and contains about 94 per cent. of copper and not more than 0·3 per cent. of arsenic. Following this is "No. 2 precipitate," containing about 92 per cent. of copper and 0·75 per cent. of arsenic. Still lower down comes "No. 3 precipitate," containing only about 50 per cent. of copper and arsenic up to 5 per cent., together with graphite from the pig iron and antimony and bismuth from the liquors. Nos. 1 and 2 are shipped for refining in this country, while No. 3 is compressed into balls and sent to the blast furnaces.

It was in the next decade, 1881–90, that the United States of America rose to the position of the world's greatest producer, and contributed about one-third of the total supply. The Lake Mines expanded their output, and both the Montana and Arizona properties were opened up and made large contributions. Spain and Portugal increased their output considerably, and in 1890 the Rio Tinto Company alone produced 30,000 tons. It was in this period also that ancient methods of production were superseded in Japan and modern processes introduced, in consequence of which that country became an exporter of copper. The credit for this is due to Professor (then Mr.) Gowland, who went out from this country and erected modern smelting plant in Japan. The decline of Chile also dates from this decade, due to the exhaustion of the richer oxide ores which were once so abundant. Much the same thing happened in South Australia. This decade was also notable for the attempt of M. Secretan, of the Société des Métaux, Paris, to obtain complete control of the output and price of copper, which failed in the spring of 1889, when the price fell £35 per ton in one day.

In the next decade, 1891–1900, American

supremacy was clearly established, and that country produced more than 50 per cent. of the world's copper. Very large increases of output took place at the Lake Montana and Arizona mines; and other districts, of which Utah was the most important, became producers. The rise and progress of the United States of America is set forth in the following table:—

Decade.	Production (tons).
1841–1850	2,400
1851–1860	37,000
1861–1870	97,100
1871–1880	186,400
1881–1890	730,700
1891–1900	1,939,940

In the final decade of the nineteenth century that country produced nearly twice as much copper as in the previous half century. The strong position established by it at the end of the nineteenth century has not only been maintained, but improved during the opening years of the twentieth century, as the following table, showing estimates of the world's smelter production in 1912, proves:—

SMELTER PRODUCTION.*

Country.	Metric tons.
United States of America	592,400
Japan	67,000
British Isles	63,200
Australia	44,900
Mexico	44,000
Germany	39,800
South America	35,000
Russia	33,500
Chile	25,000
Spain	23,300
Canada	15,500
France	13,200
Europe (other countries)	10,900
Serbia	7,400
Austria-Hungary	4,000
Italy	1,700
Total	1,020,800

Moreover, the greatly increased demand for copper created by the war has been principally met by the United States smelters and refineries which, in 1916, produced no less than about 865,000 long tons.†

Before dealing with the industry as it exists in that country to-day, a few words are necessary as to the consumption of the metal. In all some ten million tons were produced and consumed in the nineteenth century. In the early years of this period the bulk of the metal was absorbed in the engineering and shipbuilding industries, in railways, steamers, and in the applications of steam power. Later on came its use as a sheathing of wooden ships, either in the form of copper or yellow metal. The principal increase in production came, however, in the last decade, and this was due predominantly to the discovery of the dynamo and the demand for copper in the electrical industry. It is estimated that this industry absorbed then, and continues to absorb, about two-thirds of the entire copper produced. The metal is specially prepared and sold under the designation "high conductivity copper," and in its manufacture electrolytic refining followed by furnace refining is necessary in order to obtain the requisite electrical conductivity and mechanical properties. The demand for electrical purposes continues to increase, and has not been affected by the advance in prices, as hitherto there has been no substitute for copper for these purposes at anything approaching its pre-war price. In fact, as the following table shows, the tendency throughout the century which has been reviewed, apart from the decade when the Associated Smelters of Swansea controlled the price, has been to fall:—

AVERAGE PRICES OF ENGLISH TOUGH COPPER.*

Period.	Price per ton.	Period.	Price per ton.
1801–1810	£160	1851–1860	£111
1811–1820	130	1861–1870	87
1821–1830	101	1871–1880	79
1831–1840	94	1881–1890	60
1841–1850	88	1891–1900	55

It must be mentioned, however, that the price of copper has been greatly influenced by financial speculation, so that, until recent times, it has fluctuated considerably from year to year. The price of electrolytic copper has usually been from £2 to £4 per ton lower, and that of standard copper from £3 to £6 per ton lower than that of the best selected metal.

With regard to improvements in the technique of copper smelting and refining the following

* "Copper Handbook." Weed. 1915.

† Estimated by the *Metal Bulletin*.

* "A Century of Copper," p. 1.

were the more important of the advances down to the year 1880 :—

1. *In Roasting Practice.*—In 1865 the mechanically driven furnace (the Brückner cylinder) was introduced, but it was not applied to copper smelting until many years afterwards. Still later came the application of roaster gases for the manufacture of sulphuric acid.

2. *In Blast Furnace Smelting.*—Rachette, in Germany in 1863, introduced the elliptical blast furnace in connection with lead smelting. It was rapidly adapted to copper matte smelting. In 1875 the Piltz water-jacketed furnace was employed, likewise in lead smelting, and subsequently adapted to copper smelting. Although this method was found to lead to great improvements in the working of furnaces, its application was restricted for some time by practical difficulties. Ultimately the highest degree of success was obtained in America, where the plan of working elongated furnaces with water jackets was adopted.

These improvements were made on the Continent.

3. *The Principle of Pyritic Smelting.*—In 1878 John Hollway, an Englishman, conducted an elaborate series of tests with Rio Tinto ore at Penistone, the results of which were communicated to this Society in February, 1879, in a remarkable paper, entitled "A New Application of Bessemer's Method of Rapid Oxidation by which Sulphides are Utilised for Fuel." Somewhat earlier a Russian engineer, Semenikow, had been led by a consideration of the principles of the Bessemer process to utilise the heat produced by the oxidation of the sulphides in the treatment of copper mattes, but Hollway was the first to conceive the idea of what is called raw sulphide or pyritic smelting, and in his paper he enunciates clearly the principles underlying the process, and gives an account of the experimental data which support them. Professor Gowland, in his presidential address to the Institution of Mining and Metallurgy in 1907, has dealt fully with this matter, and what he says is: "England deserves the credit of the invention of pyritic smelting, although America was the first to make the invention a practical success." Between them, Semenikow and Hollway made the most important metallurgical discovery of the century in regard to copper smelting. Let me give a brief quotation from Hollway's paper, which puts in a concise form the far-reaching nature of the revolution in smelting methods proposed by him. He says: "When metals are extracted from their ores by fusion the necessary heat is always obtained by the burning of coal, coke, or other form of carbon. I wish, however, to remind you that sulphides can be made to burn in air and are thus combustible substances, while the oxides are bodies that have been already burned, which, as you know, is the conventional expression for entering into combination with oxygen. The metallic sulphides consequently are natural combustible minerals, and my object is to prove that they can be utilised as sources of heat in certain metallurgical operations.

"The most important of the mineral sulphides is pyrites, both on account of its occurrence and the extent of its deposits. The predominating constituent in this mineral species is bisulphide of iron, with which are frequently associated sulphides of copper and arsenic. . . . When iron pyrites is roasted in the open air an increase of temperature takes place in its mass, so that the oxidation continues without the application of external heat, the sulphur passing off as sulphurous acid gas while the iron is changed into ferric oxide. This process of roasting extends over a considerable space of time, and is so conducted that the heat evoked by the oxidation of the sulphides is never very manifest at any period of the operation. The sulphur and metals frequently burn to fusion, but the utilisation of the heat evolved by this burning has not hitherto been considered a subject of much importance. If, however, a rapid current of air is forced through molten sulphides the maximum temperature of the combustion is attained because all the oxygen of the air is then utilised for oxidation, and the oxidation is concentrated into the space of a few minutes instead of occupying many weeks, or, in the case of cupreous pyrites, several months. When air is forced through liquid sulphides a very energetic action takes place, and the protosulphide becomes converted into protoxide with great rapidity, thus :—

$$FeS + O_3 = FeO + SO_2.$$

In practice fluxes are present during this reaction because the protoxide of iron requires silica to form a slag; and these fluxes can be introduced with the charge of pyrites. Such poor metalliferous substances as the gangue of mines, ancient scoriæ, poor silicious copper ores, etc., containing small quantities of valuable minerals, may thus be advantageously utilised, and the copper, lead, and silver that they contain will be found in the regulus or sublimates. These materials can be introduced in considerable quantities because their specific heat is low."

When it is remembered that in every stage of the Welsh process an external fuel was required, and that about eighteen tons of coal were needed for the production of one ton of copper, it will be appreciated how important was Hollway's insistence on the need for utilising the fuel value of the sulphide ores of copper.

In the last two decades of the nineteenth century, when the United States of America became the largest producer of the metal, very great advances were made in the technique of copper smelting and refining. These have continued during the opening years of the twentieth century, and to-day the position of America is one of unchallenged—though I do not say unchallengeable—supremacy. These advances include the following developments:—

1. Great improvements in mining and ore-dressing operations (mechanical concentration).
2. The use of mechanically-rabbled roaster furnaces.
3. The manufacture of sulphuric acid both from blast furnace and roaster gases.
4. The blast roasting and sintering of sulphide fines.
5. The practical application of the pyritic smelting principle to suitable raw ores, and to practically all copper mattes.
6. An enormous increase in the capacity and output both of blast and reverberatory furnaces.
7. The recovery of metal values from the furnace waste gases.
8. The adoption of electrolytic refining followed in many cases by furnace refining with the recovery of precious metal values in the copper which more than suffice to pay for their extraction.

And, most recently of all,

9. The application of either leaching or flotation processes or both to low-grade ores, tailings, etc.

The effect of all these improvements has been to bring within the scope of practical economic development ores of lower and lower grade, and thus to lengthen the life of existing mines and to include others which, even ten years previously, were incapable of beneficiation. It must not be forgotten, however, that British workers have had an important share in these developments. At most of the great smelters in the new districts in America, now the chief seat of the industry, Welsh furnacemen are still to be found. Large numbers of them went to the United States when the centre of gravity of the industry shifted there. As Mr. Levy points out:* "To meet the enormous present-day demand for metal with the older methods and furnaces would have been impossible. The greatest stimulus to the adoption of these new and modified processes was the shifting of the chief producing centres from the older and more conservative influences to districts like the then newly-awakening west, where, with ever-increasing—almost limitless—supplies of ore available, and free from the necessity of considering the capital invested in old plants, the men in charge of the work, untrammelled by old smelting customs which might stand in the way of rapid progress, were in a position to develop their ideas with originality and vigour."

American supremacy in copper smelting to-day is founded on the possession of immense reserves of ore both in the northern and southern hemispheres of the Continent. So far as the United States proper is concerned, the chief deposits are found in four States—Arizona, Montana, Michigan, and Utah, in descending order of relative importance. The Arizona ores are low-grade porphyries. In Montana, Butte is the chief centre, famous for its veins with rich secondary sulphides. The Michigan ores, to which I have already alluded, are unique deposits of the native metal and in Utah, of which the Bingham district is the most important centre, the ore bodies consist of an altered silicious porphyry containing small grains of copper minerals very uniformly disseminated throughout the mass.

The Tennessee deposits, although yielding, comparatively speaking, a small amount of copper, are important in that they are pyritically smelted, and from the waste gases enormous quantities of sulphuric acid are manufactured. The American copper-mining groups, however, realising how essentially the industry depends for its prosperity on adequate ore resources, have in addition obtained control of rich mines both in Mexico and Chile. Probably no country in the world contains so many copper mines as Chile, and a traveller in that country readily sees why for many years it held the world's supremacy in copper production. The *Mineral Industry* for 1915 states: "A gentleman, well informed with the situation, is authority for the statement that there are probably two thousand mines that are regularly or intermittently worked." The most extensive deposit is that owned by the Chile Exploration Company, whose ore body now

* "Modern Copper Smelting," p. 11.

developed consists of more than 300,000,000 tons with an average of more than 2 per cent. of copper. In Mexico, Sonora produces from 50 to 60 per cent. of the total output, and the largest producer is the Cananea Consolidated Copper Company. The technical practice in copper smelting, which has been developed in America, is directly related to the possession by the operating companies of these immense ore reserves, and, indeed, would be impossible without them. This fact, more than anything else, differentiates American from South Wales practice. The former is based on uniformity of ore composition; the latter was built up on diversity of ore mixtures. Another important difference arises from the immensely greater scale of operations characteristic of American practice, which has caused a veritable revolution in methods of transport and mechanical handling of the materials needed for the various processes which intervene between the raw ore and the refined metal.

I do not think I can illustrate this practice better than by giving you a brief description of the works of the Anaconda Copper Mining Company. It is considerably the largest and, by common consent, one of the most efficient companies in the world. Moreover, its operations illustrate every important process whereby copper is extracted from its ores with two exceptions: (1) Pyritic smelting; and (2) the extraction of the native metal. In every other respect it is a complete epitome of the best technical practice that can be found anywhere. I shall first of all describe Anaconda practice as I found it in the summer of 1914, and then allude to certain important advances which have been made in the last three years, in consequence of which a complete reorganisation of the works has been necessary and has been attended with remarkably successful results.

The company owns about 1,168 acres of mineral claims at Butte, Montana, a great mining centre situated about 5,000 ft. above sea-level. It also owns some 13,000 acres of coal lands, large tracts of lumber land with sawmills and its own water-supply obtained from two lakes. It is operating some twenty-eight mines in the Butte area. The Anaconda mine was originally a silver producer. This gave out at a depth of about 150 ft., where copper ores were found. These were principally chalcocite, bornite, and enargite. As previously mentioned, these occur in veins. One of the mines, the St. Lawrence, has been on fire since 1889 in an extensive area about the 1,100 ft. level. This has been walled in by cement bulkheads where possible, but has never been extinguished. The copper, however, is not lost, for the sintered ore can be mined. Moreover, the mine-waters are charged with copper, which is recovered as "cement" by precipitation with scrap-iron. Mining is carried to a depth of about 3,400 ft. (vertical). The various mines of the company have immense reserves of ore of all grades. The ore mined in 1913 amounted to 4,651,445 tons, the costs being as follows:—

Mining	costs per ton	4·124 dollars
Reduction	,, ,,	1·679 ..
Transportation	,, ,,	0·320 .,
		6·123

The cost is estimated at 10 cents per pound of metal sold, but it is probable that the cost of actual production is not more than 9 cents per pound.

The ores are hauled a distance of twenty-eight miles in trains of fifty 50-ton bottom dump cars to the yards at East Anaconda. Here they are split up according to their destination, which may be either the concentrator and sampling bins or to the storage bins. In either case they are made up into trains of eight or sixteen cars according to the size of locomotive to be used, and are carefully weighed before delivery to their respective bins. The reduction works at Washoe are situated about two miles east of the city. The site includes about 240 acres, and peculiarly adapts itself in topography to the efficient handling of material. It is situated on a hillside, and thus it is possible to make the level of delivery of the product of one building the level of the charge floor of the next succeeding one.

The concentrator bins, which are of wood and steel construction, are divided as follows: Eight second-class storage bins having a capacity of 1,250 tons each; thirteen sample ore bins of 200 tons capacity each, and one coal storage bin of 2,500 tons capacity. The sampling mill is of wood construction, and consists of two complete sections, each having a capacity of 1,800 tons per twenty-four hours. The ore is taken from these bins by an electric locomotive and dropped into bins feeding the crushers. The discharge of these is elevated to the top of the building by means of bucket elevators. The stream of ore is cut four times by Brunton automatic samplers cutting out one-fifth of the amount each time and discarding four-fifths, the final result being 3·2 lb. per ton of ore crushed. The discard is elevated and dumped into concentrator ore bins, or, if it is first-class ore, it is sent to the storage

bins at the blast furnaces. The final sample is quartered, and the resulting sample dried in a steam drier, ground, bucked so as to pass through a 100-mesh sieve, and put up in four separate sample packages. One goes to the laboratory for analysis, another to the owner of the ore, and two are filed away in case of dispute.

What is called first-class ore is material which can be smelted direct, and this goes to the blast furnaces. Second-class ore, on the other hand, requires concentration of its copper values in the mill, and after this treatment goes ultimately to the reverberatory furnaces. The outline of the smelting scheme is as follows:—

Let us in the first instance follow the movements of the first-class or smelting ore, and the coarse concentrates from the second-class ore which are smelted in the blast furnaces. Anaconda was the first smelting works to adopt large furnaces of this type. The building contains three, two of which are 51 ft. and the other 87 ft. long, the width at the tuyeres being 56 in. The capacity of the smaller furnaces is 1,600 tons, and that of the larger furnace 3,000 tons of charge, per twenty-four hours. They were designed by Mr. Mathewson, the superintendent, and are very successful in operation, being much easier to handle than the old style furnaces.

The bottom of the centre of the furnace is of silica brick laid on water-cooled cast-iron plates, mounted on cast-iron columns, and has a gradual slope to each discharge spout. The smaller furnaces have two discharge spouts and settlers, the larger three. Otherwise the construction is similar. The former have eighty-eight 4 in. tuyeres, the latter 150.

The special advantage of these furnaces is that the hearth area has been greatly increased, while there are still only two ends to bind and hold the crusts. Any crusts forming on the sides can be removed by allowing the furnace to run down, the crusts either dropping down or being readily barred. They have a smaller radiating surface for the same hearth area than the furnaces previously used; they use less coke, and constitute a flexible unit, since any part of the furnace can be handled as occasion demands, and can be repaired without shutting down the furnace. This applies also to leaking water jackets, which can be changed in from six to eight hours by the following procedure. The tuyeres on the jacket to be changed and the one opposite are shut off, water is allowed to circulate until all buckstays, tuyere pipes, etc., are removed, and the jacket is ready to be pulled out. This chills a wall inside the jacket, which is strong enough to hold the charge in the furnace. The new jacket is then placed in position, all the connections made, the blast turned on, and smelting resumed. The entire end of one furnace has been shut down, jackets changed, furnace cleaned out, and operations resumed, and during all this time (extending over two weeks) the other half of the furnace was in operation.

The furnaces are charged from both sides, the doors being raised with compressed air. A "charge" train consists of eighteen cars operated by the local tramming system. The cars receive weighed quantities of the various materials from the storage bins adjacent to the building. The ore being very silicious, lime rock is the chief flux used. At the time of my visit, however, a lime iron oxide flux was being tried as well. This was found to go three times as far as the lime rock, and a further advantage was that it contained gold values which, of course, accumulated in the copper. The charge train first takes its quota of flux, then slag (from the converters and refining furnaces), then ore, then coarse concentrates, and, finally, briquettes from the briquetting plant. The briquettes are made of fine ore flue dust and concentrates, pond slum, and fine coke from the ashes of the reverberatory furnace. These materials are ground up in a pug mill and discharged into a brick machine, where they are further mixed and bricks cut out of a bar by a revolving cutter. They weigh about 10 lb., and must be strong enough to keep their form in the furnace until they reach the smelting zone. Two charge cars constitute a charge. The train, when loaded, is hauled into the blast-furnace building, where the cars are dumped by compressed air lifts. The slag and matte flow from the furnace continuously through the discharge spouts into 16 ft. settlers. These are circular and are made of half-inch steel plates lined with 12 in. silica brick. [The company manufactures its own fire and building bricks.] The slag overflows and is granulated by steam water from the concentrator, and is carried off in launders lined with blast-furnace slag plates to the dump. The matte is tapped from the settler into the 10-ton hot metal ladles of the local tramming system, and taken to the converter plant while still molten.

The matte contains from 45 to 50 per cent. of copper, which represents the highest degree of concentration which can be economically made without danger of freezing in the hearth. The slag contains about 0·25 per cent. of copper,

which is thrown away at present. Reference will be made later to the system of treatment of flue dust obtained from this and other furnaces.

THE CONCENTRATOR
(which treats all second-class ore).

This consists of two steel and wood buildings, each containing four complete sections. Seven of these are equipped with the same kind of machinery, and will treat 1,350 tons of ore per section in twenty-four hours. The remaining one can handle 1,600 tons of ore per twenty-four hours. The equipment of the former section is as follows:—

One 12 in. by 24 in. Blake crusher.
Two 15 in. by 5 in. Blake crushers.
Six coarse concentrate Hartz jigs.
One set of 15 in. by 42 in. coarse rolls.
One set of 15 in. by 42 in. fine rolls.
Thirty-six fine jigs.
One set of 15 in. by 42 in. middling rolls.
Twelve middlings jigs.
Three 6 ft. Huntington mills.
Twelve fine finishing jigs.
Thirty-three Wilfley tables.

The latter section is somewhat differently arranged. All sections have a large number of classifiers, settling tanks, dewatering tanks, elevators, and trommels of various sizes. The coarse concentrates, as already mentioned, go to the blast furnaces after being collected in bins at the upper end of the mill. The finer concentrates are carried by a system of launders to settling tanks at the foot of the building. The tank house has nine settling tanks for each section. They are 19 ft. by 19 ft. by 15 ft. high, each having a capacity of 420 tons of concentrates, and are divided up as follows: Four are for first settlement of fine concentrates, two for first settlement of $\frac{3}{8}$-in. concentrates, and three for second settlement of the concentrates. The overflow from the second settlement tanks goes to three large tanks common to all sections in that half of the mill, and finally the overflow from these tanks goes to the dirty water flume, from which it can be pumped for re-use in the mill or used at the smelter. The concentrates caught in the two $\frac{3}{8}$-in. tanks are called $\frac{3}{8}$-in. concentrates, and are treated in the blast furnaces. Those retained in the four fine tanks are called fine concentrates, 80 per cent. of which are treated in the roaster building, and 20 per cent. in the briquette plant. Those caught in the three "second settlement" tanks are called "second settlement concentrates," and are treated in the roaster building. Those finally which are caught in the three large tanks are called "tank house slimes," and are treated at the briquette plant. The tanks containing these various products are emptied from the bottom, after draining, into cars of the local tramming system, and transported to their respective destinations. It is the practice of this plant to weigh and sample the material entering and leaving every building, so that an accurate check is kept on the work of each department.

The mill practice at Anaconda in 1913, good though it was, as judged by comparison with other plants, did not succeed in retaining more than 75 per cent. of the copper values in the ore. [Gravity concentration does not, as a rule, recover much more than 70 per cent.] I allude to this now because a very great improvement in recovery has taken place at Anaconda in the last two years, and I shall have occasion to refer to this in my third lecture. Certainly it was at this stage of the operations that there was the greatest room for improvement.

The slum ponds are situated in the valley below the works, and the water, containing the greater metal values coming from the concentrator, goes to them for settlement. They vary in size, but average from 300 ft. to 630 ft. in diameter. When one pond is full, the water is diverted to another, and the former is drained as much as possible. It is then excavated by one of two travelling cableways, each having a bucket capacity of five tons. The slum is then piled outside and allowed to drain and dry, and from here it is taken by cableway and dropped into a hopper on trucks from which it runs into the railroad cars beneath, and is taken to storage bins for use at the briquette plant.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Coupling Businesses.—The road ahead of manufacturers working under official contract is moderately clear, but the prospect before all others is cloudy. Official business monopolises all the men, material and machinery that it requires, and it is from no fault of their own that the rest of manufacturers are not employed upon work recognised at the time being as of essential national interest. Their occupations have been regarded as essential enough in times past, and they will come to be so regarded again. Meantime, there is the problem to solve of how to survive with lamentably inadequate supplies of material and an incomplete skeleton force of labour, which is destined to be further reduced. It is uncertain how the feat is to be managed, but there is assurance that the extreme desirability of keeping nucleus industries together is admitted in the most authoritative quarters.

The individual would, of course, prefer to maintain intact a remnant of his individual business with freedom to ensure it in his own way. Natural predilection is all in favour of that course, but considerations of economy are said to dictate another. Manufacturers carrying on business in reduced circumstances may be urged to combine operations with a view to economies in staffs and in fuel. Proposals to close given premises and transfer their work to other mills are safe to meet some resistance. There are as many differences in points of practice between neighbouring mills as between neighbouring households, and the differences are not much easier to assimilate. Decidedly, some permanent results must be looked for from the policy of temporary syndication, should it be carried into effect.

Devolution.—It is with syndication as with other of the expedients for regulating trade during the war. Each departure from traditional custom awakens suspicion that the proposal contains more than meets the eye, and is actuated by plotters with ulterior ends to serve. Employers, no less than trade unionists, look for the restoration of the privileges that they have patriotically foregone, but there is the difference that employers have not hitherto been given the same explicit pledge. The air has been cleared, however, by the emphatic declarations given in respect of the Imports and Exports (Temporary Control) Bill. The outspoken assurances to deputations of textile traders have considerably weakened the fear that the noose of State control would be tightened and permanently fixed about their necks. The Government can have no illusions as to the real feeling of traders about the control to which they passively submit, and, given a good disposition upon its part, there will certainly be no delays in remodelling affairs upon a free basis.

State Management.—The progressive encirclement by State control is by far the most notable development of the past year. The pincers have closed around the woollen industry until the points have met. Military demand for flax has so grown that after mid-January none can be put into work without a permit. The small surplus of jute left behind after satisfying official orders is so far from free that it cannot be exported except under express permission, and such of it as is made into Hessian canvas for the normal civil market has to be sold at a controlled, although not ungenerous, price. Cotton is under the more enviable control of a Board wholly elected by the trade, and silk has the advantage or disadvantage of being uncontrolled except as all trades are controlled in regard of their general liberty. The balance of advantage under existing circumstances is difficult to strike, and in one way and another it is made pretty certain that for the rest of the war the textile industries cannot be operated for personal profit.

Direct Trading.—The decision taken by one of the most considerable Huddersfield manufacturing firms to offer its goods henceforth by direct sale to tailors is a sign of the times. The manufacturer, as he becomes more wealthy, tends to become less patient of the wholesale merchant, and the dissatisfaction of the manufacturers of fine woollen and worsted cloths has been visibly increasing for years. The example will not improbably be followed by others similarly placed, and under given conditions, the change should not be uneconomical. Beyond any part that he plays as the financier of operations, the merchant serves to bring a wide variety of goods into relatively a small compass. Not many manufacturers produce a range of goods wide enough to make their direct supply economical, and hence it so often comes that the direct-trading manufacturer turns merchant by buying from others and reselling more goods than he makes for himself. To a limited extent the merchant of sufficient capital and connection tends to become manufacturer, buying material raw and getting it manufactured upon commission. One has as good a right to extend his functions as the other, and although it might seem that these processes threaten extinction to the simple merchant, they have not hitherto worked on a sufficient scale. The merchant has easily survived, and—short always of the forming of complete combinations of manufacturing firms—it is probable that his services will always find a place.

Textile Schools.—The war has been unkind in some respects to technical education, and notably in reducing the supply of competent instructors. Lack of teachers is a greater trouble in some institutions than lack of students, for despite Army claims a large number of young men of incomplete education have been left to perform indispensable industrial work. In a degree the war has even stimulated the demand for textile instruction, for promotion in the lower ranks of industry has been unwontedly rapid; and men, thrust into posts for which they are only partly equipped, have turned to the evening schools to amplify their knowledge. It may also be that men exempted on the score of their occupation have felt it incumbent upon them to make themselves as proficient as possible at their allotted tasks. The classes for day students ordinarily attended by youths of 18 to 19 years are barer than usual, and in several centres have never been well filled by those for whom they are intended. Conceivably the end of the war will send new flocks to the day classes, by which time the needs of these students should be more fully supplied.

GENERAL NOTE.

Oil in the United States.—The principal oil-producing states in America are California, Oklahoma, Illinois, West Virginia, Texas, Louisiana, Ohio, and Pennsylvania. Over 33,500,000 barrels of fuel oil, according to the *Engineer*, are annually consumed by railways. The total yearly oil-

production of the United States is about 222,500,000 barrels of 42 gallons, and is furnished by the six great fields and a few scattered states. The greater part of the oil produced from the Gulf and Californian fields is consumed as fuel.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

January 16. — Reginald S. Clay, D.Sc., Principal of the Northern Polytechnic Institute, "The British Pianoforte Industry." Sir Frederick Bridge, C.V.O., Mus.Doc., will preside.

January 23. — Alexander Newlands, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in Great Britain (with special reference to Scotland) : its Amount and Economic Value." Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

January 30.—Sir William George Watson, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." Sir Arthur D. Steel-Maitland, Bt., M.P., will preside.

February 6.—Wm. Frecheville, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." Sir Dugald Clerk, K.B.E., D.Sc., F.R.S., will preside.

February 13.—Lord Leverhulme, "The Relations between Capital and Labour — Reasonable Hours, Co-partnership, and Efficiency." W. A. Appleton, C.B.E., Secretary of the General Federation of Trade Unions, will preside.

February 20.—Maurice B. Adams, F.R.I.B.A., "Picturesque Architecture." Sir Aston Webb, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

February 27.—Sir William H. Clark, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The Right Hon. Lord Faringdon will preside.

March 6. — A. H. Paterson, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The Right Hon. Frederick Huth Jackson will preside.

March 20. — Frank Stuart Courtney, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." Sir John Snell, M.Inst.C.E., will preside.

Dates to be hereafter announced :—

Major Sir Robert Armstrong Jones, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

George Martineau, C.B., "Sugar from several Points of View."

John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. Lawrence Ball, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

Indian Section.

Thursday afternoons, at 4.30 p.m. :—

January 17.—H. M. Surtees Tuckwell, M.I.Mech.E., "The Tata Iron and Steel Works." The Right Hon. Lord Sydenham, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., will preside.

February 14. — Sir Henry Ledgard, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India."

March 14.—

April 18.—Alfred Dickinson, M.Inst.C.E., "Water Power in India."

May 30.—Hon. Sir Dinshaw E. Wacha, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m. :—

February 5.—C. du Plessis Chiappini, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

March 5.—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. (unless otherwise announced) :—

Charles R. Darling, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical

College, Finsbury, "High Temperature Processes and Products." Three Lectures.

Syllabus.

LECTURE I.—JANUARY 21.—*Methods of Producing High Temperatures.* Special fuel furnaces—Oxy-hydrogen flame—Oxy-acetylene—Thermit—Electric furnaces.

LECTURE II.—JANUARY 28.—*High Temperature Processes.* Smelting of platinum and metals of high melting-points—Welding and cutting by oxy-acetylene flame and electric arc—Thermit welding—Production of steel and other metals by electric furnaces—Fixation of atmospheric nitrogen—Metal spraying.

LECTURE III.—FEBRUARY 4.—*Products and their Uses.* Artificial graphite for various purposes—Carborundum for abrasion and refractory purposes—Alundum and silica for chemical apparatus and refractories—Calcium carbide for making acetylene—Pure metals by thermit processes—Siloxicon and other silicon—Carbon compounds for refractories and thermal insulators—Aloxite and its uses.

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: The Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 14... Faraday Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5.30 p.m. General Discussion on "The Setting of Cements and Plasters." 1. Dr. C. H. Desch, "The Mechanism of the Setting Process in Plaster and Cement." 2. Professor H. Le Chatelier, "Crystalloids *v.* Colloids in the Theory of Cements." 3. Mr. A. A. Klein, "The Constitution and Hydration of Portland Cement." 4. Mr. G. A. Rankin, "The Setting and Hardening of Portland Cement." 5. Mr. B. Blount, "The Setting of Cement in its Relation to Engineering Structures." 6. Mr. J. Rhodin, "Note on the Colloidal Theory of Setting." 7. Mr. E. H. Lewis and M. E. Deny, "The Effect of the Addition of Suitable Slag on the Setting Properties of Portland Cement." 8. Mr. W. J. Dibdin, "Ancient and Modern Mortars."

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. Canon J. O. Hannay, "The Church and the Army."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m.

TUESDAY, JANUARY 15...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Mr. L. Gaster, "Ten Years of Illuminating Engineering: its Lessons and Future Prospects."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Captain T. S. Masterson, "The Petroleum Industry of Rumania."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. M. Flinders Petrie, "Palestine and Mesopotamia: Discovery, Past and Future." (Lecture I.)

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 6.30 p.m. Mr. J. Beaumont, "Ravenna: its Architecture and Mosaics."

WEDNESDAY, JANUARY 16...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. R. S. Clay, "The British Pianoforte Industry."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Biblical Archaeology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. S. Langdon, "Three Hymns in the Cult of Deified Kings of Ur and Isin."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Presidential Address by Mr. E. Heron-Allen, "The Royal Microscopical Society during the Great War—and after."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Lecture by Professor W. de la Mare.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. C. K. Millard, "The Problem of Birth Control, with special reference to the Public Health Aspect."

THURSDAY, JANUARY 17... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. H. M. S. Tuckwell, "The Tata Iron and Steel Works."

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. E. S. Goodrich, (*a*) "Restoration of the head of *Osteolepis*"; (*b*) "Femur of Pterodactyl from the Stonesfield Slate." 2. Mr. J. Britten, "Some early Cape Botanists." 3. Mr. C. E. Salmon, "A hybrid *Stachys*."

Child Study Society, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W., 7.30 p.m.

Chemical Society, Burlington House, W., 8 p.m.

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture I.)

Royal Institution, Albemarle-street, W., 3 p.m. Professor S. Wilkinson, "Generalship—a Battle of Napoleon (Austerlitz)." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m.

FRIDAY, JANUARY 18...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor Sir James Dewar, "Studies in Liquid Films."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m.

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portug...

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,400. VOL. LXVI.

FRIDAY, JANUARY 18, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 21st, at 4.30 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." (Lecture I.)

Fellows are requested to note that the hour of these lectures has been changed to **4.30** p.m. instead of 8 p.m., as at first announced.

WEDNESDAY, JANUARY 23rd, at 4.30 p.m. (Ordinary Meeting.) ALEXANDER NEWLANDS, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in Great Britain (with special reference to Scotland): its Amount and Economic Value." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

INDIAN SECTION.

Thursday afternoon, January 17th; the RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., in the chair. A paper on "The Tata Iron and Steel Works" was read by Mr. H. M. Surtees Tuckwell, M.I.Mech. E.

The paper and discussion will be published in a subsequent number of the *Journal.*

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

EXAMINATIONS.

Application forms for the March and May Examinations will be sent to all centres at the end of this month. The last day for receiving applications for papers for the March Examinations is Monday, February 18th.

PROCEEDINGS OF THE SOCIETY.

CANTOR LECTURES.

PROGRESS IN THE METALLURGY OF COPPER.

By H. C. H. CARPENTER, M.A., Ph.D., M.Inst.M.M., A.R.S.M.,

Professor of Metallurgy, Imperial College of Science and Technology.

Lecture III.—Delivered December 17th, 1917.

ROASTER PLANT.

The fine and second settlement concentrates then pass to the roaster building. This is of steel construction throughout, and contains sixty-four calcining furnaces of the Evans-Klepekto type. They have six hearths 16 ft. in diameter, and are 18 ft. high, and they have revolving water-cooled shafts and arms, driven by suitable gearing from the bottom. The rabbles are so set as to move the material from the circumference to the centre, and *vice versâ*, on alternate hearths, until it finally drops into the calcine hoppers immediately over the tracks of the local tramming system for transportation to the charge floor of the reverberatory building. No fuel is used other than the sulphur in the concentrates, the burning of which furnishes sufficient heat to do the calcining, except on occasions when the furnace is not hot enough to ignite the sulphur, at which times fine coal is fed in. The gases are led through brick flues into large brick and steel dust chambers, where a large proportion of the flue dust is settled. These chambers are constructed so that the bottom is a series of hoppers which permit of the delivery of the dust into cars which transport it to the reverberatory furnaces. The material which sticks to the rabble arms, centre shaft, etc., called "barrings," is barred off and sent to the blast furnaces. The wet dressing of the second-class Butte ores

produces a concentrate containing about 9 or 10 per cent. of copper from an ore containing originally about 4 per cent. Direct smelting of the original ore in a blast furnace would not yield a matte of "converter" grade, except at very heavy expense and difficulty.

The fine material obtained after water concentration cannot be conveniently treated in a blast furnace, and is smelted in a reverberatory furnace. Since the atmosphere of this type of furnace is to a great extent neutral, the charge would tend simply to melt down without much reduction of sulphur, and a low-grade matte would thus result. This is why roasting is necessary, since the roasting furnace can be operated so as to reduce the sulphur to the desired extent, and thus produce a charge which on melting in the reverberatory will give a matte of converter grade. In all modern practice the work of the reverberatory plant is controlled at the roasters. At Anaconda the sulphur is reduced from 30 to about 8 per cent., and the output of the plant is about 3,000 tons of calcines per twenty-four hours. The entire charge for the reverberatories, viz., concentrates, flue dust, and lime-rock, is passed through the roasters. This promotes the necessary mixing of the charge and has improved the yield of matte per ton of coal. At the time of my visit the reverberatory furnace plant was just about to undergo important alterations. There are two steel buildings, each containing four furnaces fired by coal burnt on a separate grate. The hearth dimensions are from 102 to 116 ft. in length by 19 ft. in width, the grate area being 16 by 7 ft., and the smelting capacity about 260 tons per twenty-four hours on natural draught. A coal-dust fired furnace, however, had been built and trials were about to take place. I shall allude to this presently.

The flame, after leaving the furnace, passes through two 375 h.p. Stirling boilers in tandem, which reduce the temperature of the gases going to the main flue to about 315° C., and by means of this 600 b.h.p. are obtained from each furnace. Mr. Demond, the company's experimental engineer, informed me that he considered that not more than 19 per cent of the heat generated by the combustion of the coal was utilised in smelting, and about 32·8 per cent. in steam-raising, the balance, viz., about 48 per cent., being lost. The velocity of the gases, according to his measurements, was about 20 ft. per second. Less than one-fifth of the total heat was therefore utilised in the right place, *i.e.* on the hearth.

The ashes and partly-burned coal which drop from the firebox fall into a stream of water which carries them over a grizzly, the larger pieces of ash going to the ash-sluice, the smaller —containing coke and unburnt coal—being sluiced to the coke-jigging plant. The coal and coke thus recovered are finally taken to the briquette plant and become a constituent part of the briquettes. Ten per cent. of the reverberatory fuel is thus recovered and utilised in the blast furnace.

Slag is skimmed from the furnaces twice in eight hours. It is allowed to accumulate until its depth is from 3 to 4 in. above the skimming plate in front of the furnace, and there it is skimmed from the end into the stream of slum water which granulates and sluices it through a launder to the slag dump. In this way about 60 tons can be removed in twenty minutes. The matte is kept down some distance below the skimming plate, making it impossible to "pull" any of it out, thus avoiding loss of copper and explosions. It is tapped from the side of the furnace and run through cast-iron launders lined with silicious material to hot-metal ladles of 10 tons capacity, and is taken by the local tramway to the converters.

The matte is of rather lower grade than that produced in the blast furnaces, and varies from 40 to 45 per cent. copper; but it is still of converter grade and can be treated without more ado. The slag carries up to about 0·3 per cent. of copper, which is thrown away.

In the next stage, the matte, whether produced in the blast or the reverberatory furnace, is Bessemerised up to blister copper. In other words, the fuel value of the sulphur is utilised to create and maintain the heat necessary for oxidising the iron, slagging it off by additions of silica, and for removing sulphur from the white metal and blowing it up to blister metal. Until recently the converters used have been of the horizontal "barrel" type, 8 ft. in diameter and 12 ft. 6 in. in length, which are operated hydraulically. They are lined with magnesite and have a capacity of about 15 tons of matte. The company, however, has developed at their Great Falls plant a new converter of much greater size, and this has now replaced the above-mentioned plant. The Great Falls converter is of the upright type and has a capacity of about 80 tons of matte, the diameter being 20 ft. The particular advantage attaching to it is that overheating, which was always a danger with the smaller furnaces, is seldom, if ever, liable to occur.

The matte is brought to the charge floor of the converter building, which is 23 ft. above the operating floor. It is poured from the ladle into a launder, the end section of which is pivoted so that it can be turned out of the way when the converter is filled. The practice is to blow the matte first of all with no flux, in order to produce magnetic oxide of iron. This deposits on the magnesite lining and constitutes a valuable protection against the corroding action of the slag. After it has formed, the necessary flux is added and blowing continued. There are two main stages: (1) the elimination of iron sulphide; (2) the removal of the remaining sulphur. The product of the first stage is a white metal, almost pure cuprous sulphide, the iron of the matte having been slagged off as ferrous silicate, and the corresponding sulphur eliminated as SO_2. The oxidation of the iron produces the greater part of the heat evolved. The flame during this period is green in colour, due apparently to the formation of ferrous silicate. When this stage is completed and the slag has been poured off—as already mentioned, this goes back for treatment in the blast furnace—the white metal is blown up to blister copper, this constituting the second main stage of the process. Much less heat is evolved in this stage, and the colour of the flame varies from red-purple to bronze-purple. It is tolerably non-luminous. The progress of the blow from matte to white metal, and thence to blister copper, is usually indicated and controlled by the appearance of the flame during the first periods, and the character of the emitted shots of metal in the later stages. It takes from seven to eight hours to blow the 80-ton charge. When ready, the latter is poured into steel ladles lined with converter slag and taken to the refining and casting furnace, where it undergoes a preliminary refining and is cast into a form suitable for subsequent electrolytic refining. Converter metal contains about 98·3 per cent. of copper. For modern electro-refining practice the crude metal must be cast into anodes, which are usually in the form of plates about 2 ft. 6 in. by 3 ft. by 2 in. thick. It is found that the metal as produced in the converters, on being cast into such plates, does not, as a rule, yield anodes which work satisfactorily in the tanks. This is largely owing to the impure and crude condition of the metal, which results in the production of plates which are spongy, coarse, and exceedingly rough and uneven on the surface. The direct employment of such metal would occasion irregularity and difficulties in the operation of the tanks, giving rise to short circuits, uneven wear, breaking off in large pieces, and similar troubles. Furthermore, the tank liquors and slimes become badly contaminated if large quantities of impurities be present in the anodes, and the deposition of good, clean metal is greatly interfered with. All these reasons render it advisable that the converter copper should, as a rule, undergo a preliminary furnace refining before being cast into anodes.

Anaconda practice is representative of the manner in which these operations are conducted, except that the enormous scale and organisation of the work are practically unique. The principles involved, however, and the general method of operation are in all essentials those of the old Welsh furnace-refining process.

There are three casting furnaces, one having a capacity of 110 tons and two of 140 tons. Two of these are in operation all the time. Owing to the high conductivity of copper, and to the fact that the functions of the furnace are either largely as a medium for simple fusion or as a receptacle for molten metal, that but little slag is produced, that no settling and separation of the fluid materials are required, and that there is no danger of dusting losses, the furnaces are built with deep hearths. These have to be very strongly constructed, and are of silica brick. The copper is poured in at the side, and as soon as the furnace contains 50 or 60 tons, oxidation by air conducted through pipes at 15 lb. pressure is commenced. When the furnace is full the slag is removed and oxidation completed; the charge is then poled back to the desired pitch and cast. The casting machine is a platform conveyor with the moulds attached and operated hydraulically. The molten copper is run into a suspended ladle, from which it is poured, also hydraulically, into the mould on the machine. When a mould is full the ladle is dropped to a horizontal position, and the conveyor is moved so as to bring the next mould into position, and the process is repeated. Twenty-five tons of copper per hour can be cast in this way.

The copper is chilled by a spray and, when "set," is dumped from the mould on to a platform conveyor, operating through a tank of water, taken to cars, weighed, and sent by rail to the refinery at Raritan, near New York harbour. A train leaves the works daily with a freight of 300 tons of these anodes on its two-thousand-mile journey eastwards.

The metal which reaches the Raritan refineries from Anaconda averages from 99·3 to

99·8 per cent. of copper. It contains also about 80 oz. of silver and 0·5 of an ounce of gold per ton. The method of arranging the electrodes in the depositing tanks is that known as the parallel or multiple system, in which all the anodes in one tank are connected to one pole of the circuit and the cathodes situated between them to the other. Each tank has thirty anodes and thirty cathodes, and there are three thousand tanks in all. In this way each tank constitutes one large anode and one large cathode, and the voltage, as measured between any two neighbouring electrodes, is the same. The system thus allows of the use of currents at low voltage and the danger of short circuiting is lessened. The tanks themselves are arranged in series. They are distributed on a series of descending levels, and the liquor flows from one set to the next by gravity through lead pipes, and is kept in circulation by pumps. The cathodes consist of thin plates of pure copper corresponding in size to the anodes. The current density is about 12 amperes per square foot, the voltage 0·2, and the temperature of the electrolyte 55° C. One anode stays in as long as three cathodes. The latter are allowed to grow until their thickness is $\frac{35}{100}$ in. They are then removed, otherwise nodulising occurs, and this sets up short circuits. The anodes last about one month, and are then taken back to the anode-casting furnace. From the sludge in the tanks are obtained gold, silver, platinum, palladium, selenium, and tellurium.

The electro-deposited copper, whose purity is from 99·95 to 99·98, still requires one more treatment. The metal, in spite of its high degree of purity, is not tough, nor is it in a shape suitable for industrial use. It is, therefore, given a final furnace-refining of the same character as that which preceded the electrolytic refining, and is cast into ingots. The refining furnace has a capacity of about 220 tons, and can be charged in two hours. From this the copper can be cast at the rate of about one ton per minute. Sometimes phosphorus is added as phosphor copper in order to ensure soundness. When intended for conductivity work the metal is cast into wire-bars of varied shape and size according to requirements. Some of these are 500 lb. in weight, and measure 7 ft. by 4½ in. square. Before casting, samples of copper are taken and drawn down into wire and tested for electrical and mechanical properties. The effect of this final operation is to reduce the purity of the copper, owing to the introduction of oxygen, to about 99·7 to 99·8 per cent.

Thus we see that the manufacture of high-grade commercial copper by the above processes requires, in the case of first-class, or smelting ore, five operations, and in the case of second-class, or concentrating ore, seven operations. The plant involved and the concentrations effected in the treatment of the second-class ore are as follows:—

Stage.	Plant.	Product.	Concentration of Copper.
		Ore	About 4 per cent.
1	Mill	Concentrates	From 9 to 10 per cent.
2	Roaster	Roasted Concentrates	
3	Reverberatory Furnace	Matte	From 40 to 45 per cent.
4	Converter	Liquid	„ 98·0 to 98·3 per cent.
5	Refining Furnace	Anode Copper	„ 99·3 to 99·8 „
6	Electrolytic Refinery	Cathode Copper	„ 99·95 to 99·98 „
7	Refining Furnace	Merchant Copper	About 99·7 to 99·8 „

[In the case of first-class ore the blast furnace takes the place of the first three stages in the above table, and concentrates direct to about 45 per cent.]

A few words are now necessary as to the treatment of the volatile products of the smelter. So far as the oxides of sulphur are concerned a small proportion of the total production is converted into sulphuric acid, which is used, *e.g.* in the leaching plant to which I shall refer presently. Almost the whole of these oxides are, however, wasted. Every twenty-four hours about 2,000 tons of sulphur oxides are discharged from the stack at the top of the plant into the atmosphere, an amount equal to almost seven times the weight of copper produced in the same time.

Connecting the various furnaces with this stack there is, however, an elaborate flue system, which is remarkable on account of its immense size. The three principal flues—viz., the blast, the roaster, and the reverberatory—are 20 ft. wide and 15 ft. high, and are of brick and steel construction. The converter flue consists of two 7 ft. by 7 ft. flues. The blast, roaster, and converter flues connect with their respective dust chambers, while the reverberatory flue connects direct with the furnaces. The lengths of the flues are as follows: Blast, 1,653 ft.; roaster, 483 ft.; converter, 703 ft.,; reverberatory, 1,253 ft.

These flues all merge into one main flue, of which the plan and cross-sections are shown on the screen. For the first 1,234 ft. this flue is 60 ft. wide, the side-walls are 20 ft. high, and the bottom is excavated at an angle of 30° from the horizontal. The remaining distance to the stack is 995 ft. of 120 ft. flue. The stack is 300 ft. high with an inside diameter of 30 ft. The top of this stack is 932 ft. above valley level.

The flue dust is drawn off through hoppers, spaced every 10 ft. in the tunnel, into cars operated by the gravity system from a set of drums placed immediately behind the stack. When the cars are loaded they are sent to the lower end of the main flue and elevated to the adjacent flue-dust bins. There are two sets of bins here—one for dust containing the desired percentage of arsenic for the arsenic plant, the other for dust which goes direct to the reverberatories. The arsenical flue dust is worked up in two stages to a product containing 99·8 per cent. of arsenic trioxide, and the residues go to the reverberatories.

I now come to certain important changes which were made in the works in 1914–1915, as a result of which the plant has been remodelled to a great extent and very remarkable improvements effected. Flotation and leaching plants on a large scale have been installed, a new roaster building has been erected, the entire reverberatory furnace plant has been rebuilt and a new method of firing adopted, and, most recently of all, the Cottrell process for agglomerating and collecting fine particles contained in gases moving at high velocity has been adopted for the recovery of mineral values from the flue dust passing out of the new roasters. The total cost of these alterations was more than six million dollars, and, according to Weed's Handbook (1916), this was entirely defrayed in the first six months of operation of the new plant. If this is the case the results must be regarded as a remarkable triumph for the judgment and foresight of the management and the skill of the company's staff.

The most striking of the improvements effected has been by the application of flotation processes to the slimes and tailings produced in the mill. In these processes, as you are no doubt aware, the sulphide particles are made to float on a froth produced by the agitation of the pulp with the addition of a small amount of oil and acid, while the gangue, although specifically lighter, sinks. Surface tension and not gravity is the principle utilised in the separation. As Mr. Ingalls has aptly expressed it, flotation is "concentration upside down." Although the commercial application of this principle has been accomplished only within the last few years, mill operators have always been puzzled, and indeed annoyed, by the action of minerals and metals under certain conditions. The amalgamator has always been bothered by his fine gold, or greasy gold, or tabular gold, which persisted in floating away from his amalgamated plates in spite of all his efforts to gather it. Operators of concentration mills have always noticed the escape of finely-ground sulphides on the surface of the water, and they have never been able to overcome that flotation tendency. In the concentration of molybdenite ore the floating tendency of that mineral has sometimes made ordinary gravity concentration impossible. Even the cyanide plant operator has often encountered a high-grade floating scum that he could never entirely abolish. Flotation is merely the recognition of the existence of these tendencies and the utilisation of them in securing better results than could be obtained by gravity concentration. Flotation concentration is "the taking advantage of the principles of surface tension and colloid chemistry, with whatever allied principles may be involved, to separate mineral from gangue by means of floating it upon the surface of water or other solutions while the gangue is induced to sink through the surface and settle separately." *

The procedure adopted at Anaconda has been described by Laist and Wiggin in the *Bulletin* of the American Institute of Mining Engineers, March 1916. Early in 1914 it was decided to test, on a large scale, the treatment by flotation of the slime and mill-tailing. For this purpose a standard-type minerals separation machine was installed at the works in May and June. This was followed by the installation of a full-

* H. A. Megraw, "The Flotation Process," 1916, p. 3.

size Callow pneumatic plant. Tests were also made with a minerals separation machine of the sub-æration type.

During the series of experiments a large variety of oils was tested. Experiments were also made using both round-table feed and tailing to determine whether it would be better to displace the round tables by flotation for the treatment of the slime, or to supplement them by flotation of the tailing. A series of tests was also made on the treatment of the mill-tailing by grinding followed by flotation to determine the relative merits of flotation and leaching for this product. In addition, flotation tests were made on mixtures of mill-tailing and slime. The round-table feed referred to is the total slime from the mill. It contains about 35 per cent. of colloidal solids and approximately 90 to 95 per cent. of the total solids will pass through 200 mesh (0·067 mm.). It assays from 2·3 to 2·6 per cent. of copper. The mill-tailing is the total discard from the mill exclusive of the slime. It is all finer than 2 mm., and from 90 to 95 per cent. will remain at 0·25 mm. It assays about 0·60 per cent. of copper.

The result of a large number of tests has caused the adoption of the following procedure:—

1. The round tables have been abolished.
2. All slime is treated by the flotation process.
3. The mill-tailings are treated by a leaching process.

As regards flotation the procedure is as follows:—

1. *The Concentration Flotation Division.*—Each section of the mill has the necessary Hardinge or tube mills for fine grinding (below the classifiers), followed by Dorr classifiers in closed circuit with these mills. Following this come four minerals separation flotation machines, having fifteen agitators and fourteen spitzkasten each, and individual 150 h.p. motors. The speed of the agitators is 225 revolutions per minute, and as the impellers are 18 in. in diameter the peripheral speed is about 1,060 ft. per minute. Each machine makes three products—a concentrate which goes to the dewatering division, a middling which is returned to the head of the machine, and a tailing which goes to waste. The concentrate is taken from the first three to five spitzkasten, and the middling from the last nine to eleven. About 6 to 8 lb. of 50° Be' H_2SO_4 per ton of flotation feed are used, together with 2 to 3 lb. of kerosene sludge acid and ½ to 1 lb. of crude wood creosote. The pulp is heated to from 60° to 70° F. by passing live steam in at the head of the machine. Each machine has a capacity of about 400 tons per day on sand and 175 tons on slime. The tailing averages about 0·25 per cent. of copper. The flotation concentrate from this is sent to Dorr thickeners, and there thickened to about 60 per cent. solids for delivery to the Oliver filters.

On account of lack of space in the mill an auxiliary plant had to be installed to handle the extra slime. This plant, known as the slime concentration department, embraces three divisions: (1) The slime thickener division; (2) the slime flotation plant, and (3) the slime concentrate thickener division. In the first named there are 160 Dorr thickeners, each 28 ft. in diameter by 3 ft. deep, arranged in batteries four tanks high. Each battery is served by a central shaft carrying eight rake arms, two to each tank, but each tank is a complete unit. This department thickens all slime made in the concentrator above the fine-grinding mills from about 3 per cent. solids to about 15 per cent. solids. Two-thirds of the thickened product goes to the slime flotation plant and one-third is returned to the concentrator flotation division, the fourth machine in each section being reserved for this purpose. The overflow from these tanks is practically clear water.

The slime flotation plant contains twenty minerals separation machines of the same size and design as those in the concentrator flotation division. Original mill slime thickened to 15 per cent. solids is fed to fourteen machines, and returned dry slime from the slime ponds is fed to six machines. The latter is first pulped in two pug mills, then through two Hardinge mills using silex linings and pebbles, and is elevated to the six machines treating this material. The table on page 147 gives the analyses of the current slime, the concentrate, and the tailing obtained in the experimental slime plant, and Messrs. Laist and Wiggin say in their paper that those are typical of the results that may be expected in the large plant.

From the flotation plant the product is elevated to the slime concentrate thickener division. This building contains five tanks, each of which is 50 ft. in diameter and 12 ft. in depth. The feed contains about 15 per cent. of solids, the spigot product about 60 per cent. of solids, and the overflow is sent to the slime ponds for further settling. It should be mentioned, however, that considerable difficulty has been and still is experienced with flotation concentrate in these tanks, owing to the extremely

Per cent.	Feed.	Tailing.	Concentrate.
Cu	2·10	0·27	12·0
SiO_2	61·00	67·70	20·0
FeO	4·10	2·70	28·0
S	4·40	1·10	
Al_2O_3	19·00	18·30	
CaO	0·60	0·70	
Ag*	1·80	0·20	
Au*	0·005	0·001	

* Ounce per ton.

persistent portion of some of the froth which cannot be made to settle, and is thus lost. To obviate this as far as possible, a circular baffle near the overflow and a large square one towards the centre of the tank have been installed, and have minimised these losses. Also, in order to break up the froth in the concentrate a saucer-shaped disc 3 ft. in diameter was constructed. This was revolved at a speed of 300 revolutions per minute inside a circular tank. The concentrate pulp was fed on to the disc at the centre, and was thrown out against the sides of the tank. The impact broke up the froth to a great extent. The difficulties experienced should cause no surprise, since they arise from the excessively fine condition of the flotation concentrate. More than half of this, Mr. Demond informs me in a recent letter, will pass through a sieve with 300 meshes per linear inch (0·044 mm. opening). In spite of losses due to this cause the total recoveries in the concentrator have, by the adoption of flotation methods, been raised from 76 to no less than about 95 per cent. This is a most remarkable achievement, and reflects the highest credit, not merely on the Anaconda Company's technical staff, but on the performance of the machines of the Minerals Separation Company.

The feed to the Oliver filters is the spigot product from all flotation concentrate thickeners. There are eleven continuous filters, each having a capacity of about 150 tons per twenty-four hours when delivering a product containing 15 per cent. of moisture. They are operated under a vacuum of about 16 in. of mercury furnished by Roots' exhausters. The product, filter cake, is delivered to one of the roaster buildings on the briquette plant. The new roaster building, No. 2, contains twenty-eight roasting furnaces of the Anaconda type — a modified wedge MacDougall furnace. They have seven hearths (one being an open hearth on top for mixing and drying the charge) 25 ft. in diameter. They have five-foot brick-lined revolving hollow shafts, carrying four arms for the two top hearths, and three water-cooled arms for the remaining hearths. The special feature of this roaster is that it contains ports between the two doors. These are intended to allow part of the air to by-pass the drop-hole, located along the outside of the hearth in order to lessen dusting. The ledge projecting from the side of the calcine rabble arm holds a permanent layer of dust in the arm, which serves to protect it from excessive heat. It has been found that a step-bearing carries the load much more satisfactorily than the roller-bearing which was used at first. The calcine is drawn into local tramway cars, and is taken to the reverberatory furnaces.

Above the roaster are now installed four Cottrell units in a structure located over the main 25 ft. by 25 ft. flue. These are designed to recover metal values in the dust carried by the gas stream. The principle of the Cottrell process, which is simply an adaptation to large-scale practice of the original discoveries of Sir Oliver Lodge, is the coalescence of the fine-dust particles under the influence of a high-tension direct current, so that they become large enough to deposit under the influence of gravity. The units employed are of the so-called "box" type. Each contains twenty-one plates 20 ft. high and 24 ft. long, 11¾ in. apart. Each plate is made up of sheets of 20-in. corrugated iron, the axes of the corrugations being horizontal. Corrugated sheets are used in preference to flats on account of their stiffness. Between the plates are hung steel chains ½ in. thick over all. The gas flows upward from the bottom, and returns to the flue by way of a common down-take, the distribution of the flow being controlled by butterfly dampers on the top of the unit. The voltage between the electrodes is about 50,000, and the total power consumed between 90 and 100 horse. Somewhere about 800,000 cubic feet of gas per minute, at a temperature of 200° C., pass through the four units, though they were designed for only half this quantity. The dust recovered is about 70 tons per twenty-four hours from the treatment of 1,500 tons of concentrate, the greater portion of which comes from the Oliver filters. It contains per ton approximately the same metal values as the calcine. A new plant is soon to be installed, which will follow the present units

somewhat closely in design. Probably, however, the walls will be of brick in order to reduce the chilling of the gases, which has a markedly disadvantageous effect on the distribution of the gas flow.

The reconstruction of the reverberatory furnace plant has brought about a striking improvement in the rate of production of matte. Mr. Demond informs me that whereas they formerly smelted from 230 to 270 tons of charge per twenty-four hours with a consumption of 60 tons of coal, they now smelt from 530 to 580 tons in the same time with 95 tons of coal. The output of each furnace has therefore been more than doubled, and the fuel ratio has gone up from about 4·2 : 1 to almost 6 : 1. Indeed, better figures than these have been obtained, for Mr. Bender,* in his paper on this subject, states that with an average daily tonnage of 542·7, the fuel ratio was 7·5 : 1. The last figure brings the reverberatory furnace almost to a level with the blast furnace from the standpoint of fuel consumption. These striking improvements are due to three factors: (1) To the increased efficiency of burning the coal in the form of dust as compared with burning it on a grate; (2) to the maintaining of a very large mass of charge piled along each side of the furnace, which increases the speed of heat absorption; and (3) to the increased size of the hearth from 112 ft. by 19 ft. to 143 ft. by 21·5 ft.

Conditions which are imperative in order to obtain successful results in coal-dust firing are :—

1. The coal, before pulverising, must be well dried down—*e.g.* to 1 per cent. or even less of moisture. This makes it pulverise better and burn more freely. Nothing is lost in drying it separately, as all the moisture must be evaporated before the coal will burn, and higher efficiency is obtained when the moisture is driven off before using. The furnace itself is the most expensive place in which to dry the coal, as the effectiveness of the whole fire is lowered by the presence of moisture.

2. The coal must be finely pulverised. The increased surface has a direct bearing on the efficiency obtained, and it is well to recognise what this increase is. Mr. Demond has calculated as follows: "The approximate diameter of a lump of bituminous coal is 3 in., and its total surface is one quarter of a square foot, while 1 lb. of coal, ground so that 95 per cent. will pass through a 100-mesh sieve and 82 per cent. through a 200-mesh sieve, has a total surface of 8,000 square feet more or less, depending upon the physical characteristics of the coal, or 32,000 times the area of the single lump."

3. The delivery of coal and air to the furnace must be controlled so that the proper quantity of each may be secured. The proper method of firing pulverised coal is to admit with the fuel the exact quantity of air required for the results to be attained.

4. The coal must contain enough volatile combustible matter to give the required combustion. About 30 per cent. volatile combustible matter is found to be a minimum.

5. The furnace must be properly proportioned and equipped, and in good condition.

6. Provision must be made for removing the ash formed.

Coal Pulverising Plant.—The coal is dumped from 50-ton cars into a receiving bin, from which it passes to two single-roll crushers. These discharge into two manganese steel chain-bucket elevators, which deliver on to a belt-conveyor which, in its turn, discharges evenly into a 1,000-ton steel bin. The coal is drawn from this bin on to a second conveyor belt through automatic feed chutes, that discharge only when the belt is in motion, and passes over a Ding's magnetic pulley to remove all nails, scrap-iron, etc., and is discharged into the boot of an elevator that feeds into three Ruggles-Coles driers fired with pulverised coal. The dried coal is discharged on to three disintegrators which crush to ¼ in. size. A screw-conveyor delivers this product to a steel chain-bucket elevator which discharges into a series of screw conveyors, and these deliver into ten steel hoppers, each of which delivers directly into a Raymond five-roll pulveriser. These are driven by individual 75 h.p. motors, and crush 97 per cent. of their product through 100-mesh. They are operated on the vacuum system. A blower placed above each mill draws the coal from it as soon as it reaches the required fineness and discharges it into a cyclone collector which partially separates the coal and air, the air returning to the mill. The excess dust-laden air from the first collectors is delivered to auxiliary cyclone collectors that discharge into the atmosphere. The dust from all the collectors is delivered by screw conveyors, in air-tight housings, to 50-ton storage hoppers, one at the firing end of each reverberatory furnace. From these hoppers the coal dust is fed into the furnaces through Warford burners, five to each furnace, using air at 16 oz.

* *Transactions* of the American Institute of Mining Engineers, Vol. LI. p. 743.

pressure. The capacity of the entire plant is 1,200 tons of coal per twenty-four hours.

The Warford burner used on the reverberatory furnaces consists of a screw conveyor in an air-tight housing bolted under the discharge opening of the furnace coal hoppers which conveys the coal from the bin to a mixing chamber, where it is thoroughly mixed with the blast air and forced through a 5-in. pipe, which in turn delivers into an 8-in. pipe, and this discharges directly into the furnace. The annular space between the 5-in. and 8-in. pipes allows the necessary secondary air to be drawn in for complete combustion of the coal, and the burners may be regulated to burn any amount from 25 to 130 tons of coal per furnace per twenty-four hours.

The blast air used in the burners is supplied by eight blowers directly connected to individual 75 h.p. motors, and capable of delivering 80,000 cubic feet of free air per minute. Six blowers are in constant operation when eight furnaces are being used. The fuel used is Diamondville coal, containing 41·4 per cent. of volatile carbonaceous matter and 8·1 per cent. of ash. It is blown into the furnace under 16 oz. of air pressure through Warford burners, five to each furnace. The advantages of this method of firing are as follows:—

1. There is a large increase of smelting capacity which makes it possible to smelt the necessary tonnages with fewer furnaces.

2. The efficiency of this method is much greater than that of burning coal on grates. In the latter there is a heat loss in transferring to the hearth the heat generated in the fire-box. This is absent in coal-dust firing, where the combustion occurs over the hearth itself. Another point is that no heat is lost in the gratings from the fire-box, which ordinarily amounts to quite 10 per cent. of the fuel value of the coal. Efficiency is also raised on account of the fact that a uniform temperature is maintained. There are no fluctuations in temperature due to firing cold fuel or to grate cleaning, or to the personal equation of the man firing the furnace.

3. Higher temperatures can be produced and maintained because the quantity of coal burned can be easily increased and there is less excess air to be heated. In grate-firing the excess is about 100 per cent., while in dust-firing only 25 per cent. of excess air is required. Also, as the volume of gases is smaller, they will remain longer in the furnace and give up more heat to the charge.

4. Less draught is required because there is no bed of coal through which air is drawn. This is an advantage because less cold air is drawn into the furnace through the side walls. The following table enables a direct comparison to be made of the two methods of firing over a period of a month, all other factors being kept as constant as possible.

No. 7 Furnace, using Diamondville coal, grate-fired.
„ 8 „ „ „ „ dust-fired.

Furnace.	Tons Smelted per Furnace day.	Total tons Smelted.	Tons Coal.	Fuel Ratio.		
					Excluding Drier Coal.	Including Drier Coal.
7	250·96	7260·31	1870·94	3·88		
8	475·75	14272·52	1984·77		7·19	7·08

It was anticipated that the coal ash might create difficulties in the working of the furnace. This is not the case. The flue connection between the furnace and the two Stirling boilers in tandem through which the gases pass on leaving it is cleaned once each day, and requires the labour of two men from four to six hours per day. Approximately, one-half of the ash floats on, or is absorbed by, the slag and does not interfere with the working of the charge. The remainder is principally deposited in the flues, and very little goes into the boilers. The average temperature of the gases as they pass to the flue is about 880° C. On entering the boilers they develop about 6½ boiler horse-power per ton of coal burned in the furnace, and their temperature is reduced to about 370° C.

The furnaces are charged along the side walls for a distance of 80 ft. from the firing end. The charge is brought in cars on an overhead track and dumped into longitudinal hoppers, from which it is fed into the furnace by 6-in. pipes equipped with slide-gates. It consists of calcine and flue dust, and is kept up nearly to the top of the side walls, thus protecting the

sides of the furnace and avoiding the necessity of fettling. The slag is continuously removed in a small stream; it is granulated by water and sluiced through launders to the dump. Matte is tapped from the skimming end of the furnace. The tap-hole plates are made of copper or cast-iron, and are set in a cast-iron front plate which is water-cooled. The tap-holes are 24 in. below the top of the skimming plate.

In October 1914 the average tonnage per day was 542·7, with a fuel ratio of 7·50.

I come now to the sand-leaching plant, which includes all the buildings and equipment necessary for the roasting and leaching of the mill-tailing, from the old tailing dump, and the recovery of copper and silver values from the solutions. The capacity of the plant is about 2,000 tons dry tailing per twenty-four hours. The tailing is excavated by a clam shell-bucket, and loaded into 50-ton bottom dump steel cars and taken to the unloading station, where it passes through a grizzly on to an inclined belt conveyor, which delivers it into storage bins of 6,000 tons capacity. From these bins it is drawn as required on to a system of belt conveyors that carry it through a tunnel and incline and deliver it into 20-ton hoppers over the roasting furnaces.

The roaster building contains twenty-eight modified MacDougall furnaces. Each furnace has two fire-boxes, one each on opposite sides of the third hearth. The material is given what Mr. Laist calls an "oxychloride roasting." * The roasted material is cooled in a rotating drum and wetted, to prevent dust, before being delivered to a system of belt conveyors that carry it into the leaching-tank building. The latter contains fifteen redwood tanks, each 50 ft. in diameter and 14 ft. deep. Ten of these are for leaching, and have filter bottoms. About 1,050 tons of roasted tailing constitutes a charge. This is distributed evenly over the area of the tank by a drag conveyor revolving about a central axis. Leaching is carried on by downward percolation of a hot solution of salt and sulphuric acid. The addition of the salt is made primarily to dissolve the silver, which would not be effected by the action of sulphuric acid alone. The solution, after passing through the charge, is sent to the solution storage tanks. The tailing from the leach is washed with water and sluiced through gates in the tank bottom into a launder leading to the tailing dump. Five of the tanks in the building are for solution storage purposes, and are at a lower level than the bottoms of the leaching tanks. The solutions are elevated by vertical shaft hard lead centrifugal pumps.

Immediately north of the building are three concrete precipitating launders, each 180 ft. long and 4 by 8 ft. in section. These are kept filled with scrap-iron and strong copper solution from the solution storage tanks is allowed to circulate through them until all the copper is precipitated. The precipitate is taken to the briquette plant and from there goes to the blast furnaces.

Mr. Laist, the metallurgical superintendent at Anaconda, estimated in 1913 that the tailings material could be roasted and leached for not more than 70 cents per ton, which means that copper can be made from tailings yielding only 10 lb. per ton for 7 cents per lb. The recovered silver was estimated to pay for shipping, marketing, and refining, plus about 0.5 cent, making the net cost of the copper about 6.5 cents per lb. Those costs are made possible by the fact that the material in question is already mined, crushed, and sized, that cheap acid is available, made from the roaster gases, and that the operations are on a very large scale. In the experimental plant (an 80-ton per day unit) about 85 per cent. of the copper and 93·5 per cent. of the silver were recovered. Data as to recoveries in the large-scale plant have not been published.

I must, in conclusion, say a word about the laboratory, testing, and research departments. All samples taken in the works, and at the sampling mills, are sent to the laboratory and analysed there for such elements as copper, gold, silver, lead, zinc, iron, lime, sulphur, alumina, silica, and the rarer metals. About 18,000 actual determinations are made each month. The work of the testing department includes the investigation of metallurgical and other technical problems relating to the various operating departments. Its equipment provides for the testing of building materials of all kinds, concentration tests, temperature measurements, gas determinations, measurements of air, water, etc. The research department does all the experimental work connected with new processes, and puts them on a commercial working basis before turning them over to the operating department. Complete laboratory leaching and flotation apparatus are parts of this equipment. In addition there is a large assembly room, where meetings relative to the operation of the plant

* Full details are given in the *Transactions* of the American Institute of Mining Engineers, Vol. XLVI. pp. 362–377.

are held, and discussions take place. It has the equipment of a good lecture room.

Some years ago a "Safety First" department was instituted, and this has become a permanent feature of the works organisation. Committees have been appointed to discuss methods of providing safer and more healthful working conditions for the employees. There is a permanent general committee, composed of officials of the company, and there are departmental committees composed of members of the operating staff. The head of each department is the permanent chairman of that committee; the other members are changed once in three months. The office of safety engineer has been created, and a magazine—*The Anode*—is published monthly to offer helpful suggestions and to record what is being accomplished by this and other similar departments. Each department has a bulletin board for illustrations of causes of accidents and methods of their prevention. Departmental first aid teams have been organised, and competition between them is very keen. A completely equipped department to deal with fire outbreaks is maintained.

Finally, permit me to record an incident during my visit to Anaconda. The general manager, Mr. Mathewson, received me very kindly, and when he was about to take me round the plant he said: "We quite understand that you are not an expert on the practical side of the metallurgy of copper, but *we don't consider we know everything here;* and if in the course of your stay with us you have any suggestions to make with regard to what appears to you to be possible improvements in our methods or processes, we shall be most pleased to consider them." I have visited many other works in the course of my life, in this and other countries, but I cannot remember having had a remark of that kind made to me at any of them. I venture to suggest to you that there is a direct connection between the attitude of mind revealed in Mr. Mathewson's request and the high degree of efficiency and skill which characterises every department in the Anaconda works. I will go even further, and say that, in my opinion, the connection is one of cause and effect, and that the future lies in the hands of works which are conducted in this spirit.

I had hoped to deal briefly with present-day practice in the extraction of native copper at Calumet, in pyritic smelting at the Tennessee Copper Company, and in leaching at Chuquicamata. Time presses, however, and I must confine myself to a brief reference to the last named, whose special interest lies in the fact that electrolytic copper of a high degree of purity is obtained from the ore in only three stages.

The mine of the Chile Exploration Company, situated at Chuquicamata, is, as regards tonnage and contents of valuable metal, one of the greatest known copper deposits in the world, and is unique in that its principal copper mineral, brochantite, is mined on a commercial scale in no other locality. This property is situated on a branch of the Antofagasta and Bolivia railway, about 160 miles north-east of Antofagasta. The high point of the mine lies at an altitude of 9,890 ft., while the extraction plant lies 9,023 ft. up. Deposits were worked by the ancient Indians long before the Spanish conquest. They used the minerals atacamite and brochantite for ornamental purposes rather than for general utility. Later on the Spaniards operated the mines in a small way, and in recent years English and Chilian companies have done a considerable amount of mining both underground and in open pits. In 1912 the property was acquired by the American firm of Guggenheim's, and drilling was started. Three years and one month later the plant was started on a commercial scale. In that time the mine was opened up for steam-shovel mining, a railway for transportation of the ore was built, and a plant of 10,000 tons daily capacity was designed and erected in a desert 5,000 miles away from the base of supplies.

The ore reserves on April 25th, 1915, were estimated as follows:—

	Tons.	Percentage of Copper.
Oxidised ore .	204,384,409	1·952
Mixed ore . .	65,787,332	2·983
Sulphide ore .	33,129,047	2·477
	303,300,788	2·233

say, 2·00 per cent. of copper.

The total copper reserves are, according to this estimate, more than six million tons—truly a colossal figure, and one estimated by Mr. Pope Yeatman, the company's engineer, to be well within the mark.

A typical analysis of the oxidised ore is as follows:—

Moisture	0·30	per cent.
Silica	67·48	,,
Lime	0·61	,,
Copper oxide (CuO) . .	2·66	,,
Chlorine	0·40	,,
Nitric acid	0·05	,,

(SO_3)	Sulphuric acid	1·76	per cent.
	Sulphur (sulphide)	0·03	,,
	Alumina	13·39	,,
	Ferric Oxide	1·86	,,
	Magnesia	0·24	,,
	Manganese dioxide	0·02	,,
	Sodium oxide (Na_2O)	3·46	,,
	Potassium oxide (K_2O)	0·84	,,
	Loss on ignition	6·80	,,
	Total	99·90	

The ore near the surface is higher in chlorine and nitrates. What makes the process chosen particularly applicable for the Chuquicamata ore is the fact that it carries itself more than enough sulphuric acid for the solution of the copper, and that on precipitation of this from the solution more than sufficient acid for the leaching of the next batch is regenerated, which allows the discarding of solutions if necessary, and thus avoids their fouling by continual use.

Experiments proved that very little iron, silica, or alumina goes into solution, and that it is possible with the average ore to use the same solution as many as a hundred times without ill effect. The method of extraction was worked out under the direction of Mr. Cappelen Smith. Briefly it is as follows :—

The plant is designed for a capacity of 10,000 tons of average grade ore per day. The latter is crushed to about ½-in. mesh, and leached with sulphuric acid. The greater part of the chlorine is eliminated by treatment in tube mills with metallic copper. The remaining copper is precipitated from solution by electrolysis, and the cathodes are melted into commercial bars. The cuprous chloride formed in the dechloridising drums is worked up into copper, either by smelting or by dissolving the chloride in salt and electrolysing, or by precipitating as cement copper with scrap-iron. In the original plant magnetite anodes were used in the electrolytic process. They proved very brittle and numerous breakages occurred. A substitute which has proved satisfactory on the whole is duriron, a high silicon iron alloy. It is not entirely unacted on, but from fifteen to twenty times its weight of copper can be deposited before it is corroded away. Duriron anodes have an advantage over magnetite in their mechanical strength, but they have a much higher over-voltage, which is a decided disadvantage, and about 15 per cent. more electrical energy is required for the deposition of the same quantity of copper. The conductivity of the copper produced is from 100·5 to 101 per cent. Matthiesslu's standard.

A very good description of the metallurgical operations of the plant is given by Mr. Rose in the *Engineering and Mining Journal*, 1916, pages 321–326. The particular interest attaching to the processes at Chuquicamata is that for the first time, and on a really large scale, lixiviation and precipitation methods have been adopted for the extraction of copper in a way which recalls those in use for that of gold and silver. From start to finish the process is one of hydrometallurgy, and pyrometallurgical processes—apart from one alternative method of working up the cuprous chloride—are entirely absent. Although the operations of the plant have not yet been brought up to the anticipated capacity of 10,000 tons per day, this is not on account of any basic defect of the process, but is rather due to the usual troubles encountered in starting any new metallurgical plant.

A few words in conclusion as to present-day tendencies in the metallurgy of copper. I think I cannot do better than quote some words recently written by Mr. Lawrence Addicks,* one of the foremost copper metallurgists in the world. He writes :—

"The unprecedented market for copper during 1916 has given a tremendous stimulus not only to the production of the metal and consequent expansion of the reduction plants, but also to the further development of the metallurgy of lean ores. . . . A table of average contents of ores treated in the last ten years would show an astonishing diminution year by year, and with the increasing attention to the recovery of by-products such as sulphuric acid and some of the minor metals associated with copper, it will soon be difficult to define a copper ore at all. The advance in copper metallurgy in 1916 may be briefly summarised as having been striking in three directions : Flotation, leaching, and sulphuric acid manufacture from smeltery smoke, all of which are more or less closely inter-related. Flotation and leaching, though far apart at one end of their application, rub elbows rather closely at the other end, and sulphuric acid—which can be produced so cheaply as a by-product from waste gases at a neighbouring smeltery—has become the desideratum of the leaching plant. . . .

"The revolutionary effects of flotation continue to be felt in both ore dressing and smelting, as shown by the development of fine-grinding machinery, and of methods of drying and smelting concentrates of excessive fineness. The

* *Engineering and Mining Journal*, 1916, pp. 51–52.

whole flotation question appears to be clarifying. On the theoretical side the controversy as to its *modus operandi* has led to a general investigation of the application of colloid chemistry, which is yielding many data of value in other lines. . . . Practically the possibilities and limitation of flotation as a metallurgical process are more clearly understood than they were a year ago. What it can do on a sulphide ore is shown by the increase in the concentrates recovery from 82 per cent. under the highly developed methods of the old wet concentration to 96 per cent. after adding flotation. On mixed sulphides and oxides the feeling is now that the latter can be better handled by a separate hydro-metallurgical treatment. When acids and soluble sulphides are added as flotative agents with the object of coating oxidised material, flotation is really sailing more or less under false colours, as most of the additional recovery seems to be due to the dissolving of copper in the acid, and subsequent precipitation as sulphide which is straight leaching; and as these reagents tend to react rather unfavourably on the legitimate recovery of the sulphide minerals present, it appears that the leaching operation should be conducted separately.

"The clearer conception of the limitations of flotation methods already mentioned has led to a renewed interest in leaching, which for a time had suffered from arrested development. The companies in the south-west producing concentrates with some oxidised values, are practically all experimenting along leaching lines for the recovery of these values. One scheme that seems to have possibilities is that of dissolving these values in dilute sulphuric acid and then precipitating them upon iron, recovering the cement by flotation without any attempt to separate the liquid from the pulp. This avoids having to meet the difficult question of filtration or otherwise dewatering a more or less colloidal slime. Flotation is also being considered as an adjunct in the Lake Region, and while a year ago it appeared that flotation controlled the sulphides and leaching the oxidised propositions, and that the mixed ores would be fought for by the two methods with a strong leaning towards the former, it now seems probable that this middle ground will be handled by both methods used on complementary rather than competitive flow sheets.

"The exceedingly fine state of physical subdivision of flotation concentrates, together with the large and increasing tonnage produced, has introduced problems in treatment which are bringing about a general overhauling of methods. While a reverberatory thrives on fine material, even it expresses some surprise at a charge running from 100 down to 500 mesh. This has caused the possibilities of leaching to be considered as a means of treating the concentrates themselves, and it is quite possible that the metallurgy of copper may develop along quite new lines in the next few years."

You will see, therefore, that the general trend of the metallurgy of copper in most recent times has been towards a substitution of pyrometallurgical by hydrometallurgical methods, and it is to be expected, in view of the decidedly promising results which have been achieved, that this tendency will be still further accentuated. If such proves to be the case, the similarity between the methods of extraction of copper on the one hand, and gold and silver on the other, will become more and more pronounced, and the significance of this should be realised, for it will mean that the copper industry has reached a level of uncommonly high technical efficiency. The great importance now attached—and rightly attached —to the necessity of working the ores, not only for their copper values but for *all* values which they contain, is also of a significance not easily to be exaggerated, because it involves the conclusion that a far wider range of raw materials will be brought within the scope of economic exploitation than would otherwise be the case. It can hardly be doubted that within a short time certain ores containing not more than 1 per cent. of copper will be worked for that copper. Not only therefore will it be possible, owing to increased extractions, to conserve the world's ore resources, but the life of the industry will thereby be correspondingly lengthened and thus rendered more stable. And even though it is the case that the centre of gravity of the industry is in the United States of America, and perhaps is destined to stay there, we in this country may feel a legitimate pride in the fact that the genuine pioneering work of such men as John Holway in pyritic smelting and the Bessemerising of mattes, Parkes, and later the MacDougall brothers, in the design of roasting furnaces, Elkington in electro-refining, Oliver Lodge in electrostatic precipitation, and most recently of all Sulman and Picard in flotation, has had a revolutionising and most beneficial influence on the scientific development of that industry.

SIXTH ORDINARY MEETING.

WEDNESDAY, JANUARY 16th, 1918; SIR FREDERICK BRIDGE, C.V.O., Mus.Doc., Organist to Westminster Abbey, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Armstrong, Lieut.-Colonel J. A., R.E., London.
Ashford, John, M.I.Mech.E., India.
Brecknell, Henry Edwin Frank, Bristol.
Brown, Lieut.-Colonel F. Leslie, D.S.O., South Africa.
Bunker, George R., New York, U.S.A.
Butcher, Arthur Douglas Deane, Egypt.
Butler, William, Pennsylvania, U.S.A.
Carnt, Engineer-Commander Albert John, Peterborough.
Carruthers, Engineer-Captain David John, R.N., Sevenoaks.
Dommett, Lieutenant William Erskine, R.N.V.R., Bedford.
Geejgarh, Chief of (Thakur Sahib Kushal Singh), India.
Gill, Harry, Kinlochleven, Scotland.
Graham, Alfred H. Irvine, Assoc.M.Inst.C.E., Surbiton.
Heckford, Arthur Egerton, Birmingham.
Hood, James Maclay, Glasgow.
Hugon, G. R., Manchester.
Hunter, Sir John, K.B.E., Dumbarton.
Hurren, Frederick Harold, Coventry.
Ingle, W. L., J.P., Leeds.
Kemp, Henry Thomas, Abbey Wood.
Kreglinger, Albert, London.
Leigh, E. B., Chicago, U.S.A.
Maxwell, Robert W., Surrey.
Morch, Jacob, London.
Owen, Alfred Ernest, Darlaston.
Pearson, John Andrew, Toronto.
Pierce, Edward Lily, Syracuse, U.S.A.
Pinckard, Mrs. R. A., London.
Richardson, Ralph, Weybridge.
Saunders, Samuel Edgar, M.I.N.A., Isle of Wight.
Scott, Thomas Henderson, Assoc.M.Inst.C.E., Trinidad.
Simms, William Archerr, Swansea.
Smith, Major S. Heckstall, London.
Tucker, Percy Earle, Yeovil.
Twiggs, Alderman H. W., Bristol.
Waddington, George, London.
Wakefield, Alderman Sir Charles Cheers, Bt., London.
Walker, Henry T., London.
Welch, Henry John, Bromley, Kent.
Wilkinson, Samuel Blaze, Northampton.

The following candidates were balloted for and duly elected Fellows of the Society:—

Barnett, Samuel, London.
Bewsher, Joseph Ponsonby Horatio, Croydon, Surrey.
Bradley, Major Benjamin, Harpenden.
Carter, Wilfrid George, Kingston-on-Thames.
Connal, Allan Ramsay, A.M.I.E.E., East Sheen.
Copley, J. W., Caterham.
Crewdson, Alfred, Alderley Edge.
Foley, Gerald Henry, R.F.C., London.
Gourlay, C. G., London.
Haslam, William Gilbert, J.P., Derby.
Haynes, Ernest, London.
Lyddon, George Edward, A.M.I.Mech.E., London.
Matthey, George Cowper Hugh, London.
Murphy, William Bernard, Peterborough.
Rawlinson, H. W., London.
Smith, Henry White, Bristol.
Smith, John Sugden, Bradford.
Stewart, Samuel, London.
Thornton, John Edward, London.
Walsh, Frank Ford Peregrine, F.R.G.S., London.

The paper read was—

THE BRITISH PIANOFORTE INDUSTRY.

By DR. REGINALD S. CLAY,
Principal of the Northern Polytechnic Institute.

Music is, perhaps, the oldest of the Arts. We read, for instance, of "Jubal, who was the father of such as handle the harp and organ," and stringed instruments played with the hand are undoubtedly very ancient. They appear on Egyptian sculptures, and one at least has been found in an early Egyptian tomb still retaining some of the strings intact. The keyboard was at first applied to the organ, possibly as early as the second century, although this is uncertain. The small portative organs with keyboards were certainly in use in the thirteenth and, perhaps, twelfth centuries for processional work in the churches.

Towards the end of the next century two-stringed instruments—the exaquir, or echiquier, and the doucemelles—were made, almost certainly with a keyboard, and, if so, these were the parents of the modern piano. They were followed by a series of better known instruments. The first of these, the clavichord, was invented, apparently, somewhat before 1500. In this instrument the string was struck by a tongue, called a tangent, which was held against the string so long as the sound was desired to

be maintained. The tangent formed a temporary bridge, the string vibrating between it and the bridge on the soundboard. Beyond the tangent the string was permanently damped by a narrow band of soft stuff, so that as soon as the tangent was removed from the string the sound ceased. The wires were all brass, apparently of equal length; there were several soundboard bridges; and more than one tangent struck the same string at different distances from the bridge, and so produced notes of different pitch. Thus there were more keys and tangents than there were strings. A true vibrato effect was possible with this instrument.

The second instrument was the virginal, or spinet, in which the sound was produced by plucking the wire with a piece of quill. This also dates from the end of the fifteenth century, and may be older than the clavichord. The immortal Pepys bought a spinet in 1688. He says: "At noon is brought home the espinette I bought the other day of Haward costs me £5." Other English makers were James Hitchcock and Keene. The spinet was a comparatively small instrument with the strings running more or less parallel to the keyboard.

In the third of these early instruments, the harpsichord, the strings ran at right angles to the keyboard as in the ordinary straight string grand piano, and the shape of the instrument was very similar to that of the grand. The sound was produced in the same way by plucking the string. This method of producing sound continued for three centuries. It is, of course, obvious that no variation in intensity could be produced by striking the key harder (as in the ordinary piano); so, in order to give variety in the harpsichord, stops were added by which, on the striking of a key, different sets of jacks could be brought into play which plucked other wires which might be the same pitch or a pitch an octave higher, or even occasionally an octave lower; also leather was sometimes substituted for the quill to produce a softer tone, and the more costly had two keyboards. Venetian shutters were added to vary the loudness. There is a fine example, dated 1521, in the South Kensington Museum. The great harpsichord-makers of this century were Burkhardt Tschudi and Jacob Kirchman, both of London, the founders of the houses of Broadwood and Kirkman. These instruments continued to be made up to the end of the eighteenth century.

The piano itself was invented about 1709 by an Italian, Cristofori, who was a musical instrument maker to the Duke of Tuscany. It was fully described in the *Giornal di Litterati d'Italia*, Venice, 1711. It was invented, no doubt independently, by a Frenchman, Marius, in 1716, but his action does not appear to provide any means for preventing the hammer remaining in contact with the string after the blow was struck.

A third inventor was Christopher Schröter, in 1717. His action had no hopper, the travel of the key was limited, the hammer finishing the last quarter-inch of its movement by its own inertia, so that the touch must have been poor.

The Cristofori piano apparently died out in Italy, but Gottfried Silbermann, of Dresden, Saxony, possibly a pupil of Cristofori, started making these instruments in Germany, copying the Cristofori piano exactly. The Seven Years' War (1755–62), through the devastation of Saxony, destroyed the industry, and twelve Germans—called, according to an old shop tradition, "the Twelve Apostles"—landed in England about 1760, among them being Zumpe, Backers or Beckers, and Geib. These helped to found the piano industry in this country. Zumpe designed the square piano, of which he sold great numbers. The action was a very simple one, and the instrument was sold at a comparatively low price. Kirkman, who had started in England in 1740 as a harpsichord-maker, also took up the manufacture of pianos about the same time. He died in 1778 worth nearly a quarter of a million. Evidently the trade was a very lucrative one in those days. So also did Tschudi take up the manufacture of pianos. He was born at Schwanden in Switzerland in 1702. He came to London in 1718 as a cabinet-maker, and he entered the firm of Tabel, who was a harpsichord maker. In 1732 he started on his own account at 33, Great Poultney Street. Early in the fifties John Broadwood, who was born at Cockburnspath in Scotland in 1732, and was a joiner by trade, entered his factory. He was evidently a valuable asset to the firm, as he was shortly after made a partner and married his employer's daughter. He was a man of great ability and distinction; he kept open house, at which the musicians and other artists of the day congregated. He was one of those who appreciated the value of science, using Dr. Gray and others to assist him in improving his pianos. In 1795 he admitted his son, James Tschudi Broadwood, to partnership. He died in 1812 at the age of eighty. His grandson, Henry Fowler Broadwood, was another who greatly assisted in developing this firm, and he also died at the great age of eighty-two in 1893.

Another of the oldest firms responsible for the development of the British piano industry is that of Collard and Collard. This firm has grown out of that of Longman and Broderip, which was established in 1740 as a music publishing firm. They were joined and ultimately taken over by Muzio Clementi, the composer and virtuoso. Later, he associated himself with F. W. Collard, and, when he retired, the firm became Collard and Collard. The inventive genius of F. W. Collard, joined with the musical criticism and the reputation of Clementi, made the rapid progress of this firm. Other old firms were Challen, established 1804 by William Challen, a member of an old Sussex family, whose genius for mechanical work impelled him to try his fortune in London, where he started in Great Titchfield Street, in partnership with a Mr. Hollis, as a piano maker, followed by his son, Charles Challen, who lived till 1909; Chappell and Co., 1810; Eavestaff and Sons, 1823; Cramer and Co., 1824; Pohlmann and Sons, 1828; B. Squire and Sons, 1830; Rogers and Sons, 1834; Hopkinson, 1835; Strohmenger, 1835; J. Brinsmead and Sons, 1837; and Allison, 1837.

The number of firms engaged in the industry has slowly increased, until there are at the present time over one hundred and thirty pianoforte manufacturing firms in England, not including the large number of firms engaged in the construction of special parts, as, for instance, the action, keys, iron frames, wrest pins, wires, etc. The action and key makers usually supply the piano manufacturers direct, but in the smaller parts the manufacturers deal through the supply houses. The majority of the pianos naturally are sold to the public by dealers, of whom there are, of course, a large number in every town of any size, and the total of these is therefore very much greater than the number of piano manufacturers, so that the industry is one of considerable importance.

I have not been able to obtain statistics showing the growth in the output of British pianos from the commencement, as I had hoped might have been possible, but from the Census returns I find that in 1911 in Great Britain there were 14,115 men and 312 women engaged in the manufacture of pianos and organs. The total number engaged in the manufacture of musical instruments in the same year was 15,889 men and 565 women. The Census returns before 1911 do not separate those engaged on musical instruments, but as the above figures show that the piano and organ firms employed the bulk of the labour, the statistics for the musical instruments generally must obviously show pretty closely the growth of the piano industry. These figures which are shown on the screen date back for the last sixty years:—

In 1913 the total pianos sold by the English piano manufacturers amounted to 117,665, of which 9,251 were exported and 107,814 were sold to the home market.

The number of men employed by the piano manufacturers was 9,750. This number does not, of course, include those engaged in the subsidiary trades, which accounts for the greater part of the difference in the figure and the 14,115 mentioned above. The retail value of the instruments was, roughly, about £4,000,000.

According to an old book, the number of pianos made in 1851 was 23,000, valued at £1,000,000; in 1853 the number increased to 27,740, valued at £2,840,000. It is stated that there were 200 makers, and that there were forty separate branches of the trade. The total tension of the strings is given as between 11 and 12 tons.

Our great competitors up to 1870 were the French. For instance, in 1863 the value of the pianos imported from France was £103,458 out of a total import of £111,228. The total number of pianos imported in 1865 was 2,421, and by this year the total value of the imports had fallen to £66,772, and by the following year it had again fallen to £32,215. The Board of Trade did not give the value of the pianos imported separately from the musical instruments between 1870 and 1904; but by the latter date it had increased some tenfold to £648,701. It continued to increase up till 1906, reaching a maximum then of £706,244; in 1909 it declined slightly to £569,250, rising again to just over three-quarters of a million sterling in 1913.

Some statistics of the imports and exports have been kindly prepared for me from the Board of Trade returns by Mr. White.

The total number of pianos made in 1860 was stated by Edgar Brinsmead, in his book published in 1870, to have been 35,000. So that, even in spite of the foreign competition

and the lack of initiative of the British manufacturers, the trade has very considerably increased in the last forty years; but I venture to say that that increase is not nearly as great as it might and should have been. The export trade in particular is almost insignificant. According to Dolge, the output of American pianos in 1911 was 350,000, and of German 170,000, of which 20,000 were exported to England.

The manufacture of the pianoforte appears to have been a very healthy industry. I have already mentioned the names of two makers who passed the age of eighty, and the Census returns giving the ages of those engaged in the trade are interesting, especially when it is to be remembered that in 1911 the pernicious system of seasonal employment for the workmen was the practice in a large number of firms—that is to say, that these firms, instead of maintaining a steady output through the year, ran their factories at a high pressure for six months and then paid off a large number of their hands. Obviously such a system would very greatly deter good men from taking up the trade.

AGES OF EMPLOYEES IN PIANO AND ORGAN FIRMS IN LONDON IN 1911.

The English square piano was, as I have said, introduced by Zumpe between 1760 and 1765. The action was a very elementary one, as you have seen. Broadwood improved the piano by moving the wrest plank from the side to the back, but he still used the same action. It was John Geib, another "apostle," who in 1786 re-introduced the hopper invented by Cristofori and applied it to the square piano; pianos with this action were first made by Longman and Broderip. About the same time Backers invented the so-called English action which, developed by Stodart and Broadwood, remained almost unchanged in England for nearly a hundred years—in fact, long after the beautiful action invented by Sebastian Erard in 1823 had been universally adopted abroad.

The use of a single wire double length to serve as two strings was invented and patented by Collard in 1827. About the same time the down bearing was introduced, that is to say, the bending of the wire as it passes over the bridge so as to produce pressure on the soundboard. The repetition movement was patented by Broadwood for their grand action, invented by Southwell, an Irishman, who had previously invented the Irish damper.

I might point out, in passing, that the question which has come to the fore again as to the possibility of affecting the tone by the method in which the key is struck, was discussed as early as 1854, when Dr. Lardner said: "the keys can produce no effect whatever upon the string, except by imparting more or less projectile velocity to the hammer. The player may work his hands and his arms, he may raise them two feet above the keys and throw them down upon the keys; he may gesticulate as though he were engaged in a Herculean task, but the strings will not sympathise with his struggles, and will respond with no more effect than they would if the keys were put down with the same celerity and promptitude by the fingers of an infant."

The modern upright piano was the invention of an Englishman, John Isaac Hawkins, who had migrated to Philadelphia. He patented it in 1800. Up to this time the upright pianos had, like the upright spinets and harpsichords, been merely horizontal instruments turned up on the broad end on a stand. In Hawkins's piano the strings descended below the keyboard, and the bottom of the instrument was upon the floor. There was a complete iron frame, within which the belly was suspended independent of the case. It was full of new ideas, including a hopper action, iron rods at the back to balance the strain of the wires, and a system of tuning by mechanical screws.

The upright pianos were mostly fitted with the sticker action invented by Southwell in 1807.

The action now used in all upright pianos was the invention of an Englishman, Wornum, in 1826. But again the sticker action of Southwell was adhered to in England long after the Wornum action had been almost universally adopted abroad. Wornum made an upright piano in 1811 with diagonal strings. Another great improvement that we refused to accept for many years was the iron frame, although we appear to have been the first to use iron to strengthen the wood frame. This conservatism seems to have paralysed the improvement of the piano for at least thirty years. Up to 1860, or even 1870, we were well to the front, and most of the improvements were due to

English firms; but, in common with many other industries, we allowed this one also to fall behind during the last part of the nineteenth century. The first seventy years of that century is one we can look back upon with pride. The application of the steam engine, which Watt had made efficient, to engineering, to textiles, to locomotion, and to industry generally, associated with the names of Murdoch, Stephenson, Brunell, Arkwright, and Compton; the developments of electricity associated with Faraday, Wheatstone, Kelvin; the supremacy which we had at sea, the development of our Colonies, and the general prosperity of the country, had brought fortunes to the men who owned businesses. The men who had originally built up the businesses were gone; their descendants were some of them old men, who had grown into ruts and would have no changes; or, if young, they had come into the business with little knowledge of the practical side and still less of the science which underlay it, and with no appreciation of the value, nay, the necessity, of the assistance of science if the business was to progress. Our competitors abroad, on the other hand, both on the Continent and in America, were fully alive to the aid which science could render. The results of this disastrous blindness in the chemical, optical, and even electrical engineering industries, were acutely realised almost immediately after war was declared. All this is almost equally true of the piano industry. This has grown continuously up to the date given with little foreign competition, and the larger firms in the industry had realised large fortunes. The industry has indeed continued to grow since, but not to the extent it should have done, considering the great demand that the spread of education had produced, so that not only the middle class, but even the artisan home has grown to be incomplete without its piano. It was not until our markets had been seriously invaded that the English firms realised that they must change their methods and adopt the improved actions, iron frames, higher tensions with wires of better quality, and the general improvement in tone, that their competitors had evolved. In fact, we were behind, and whereas formerly the improvements in piano construction had, during the first part of the century, for the most part originated here and been copied abroad, during the last fifty years they have mostly originated abroad and been—sometimes after a long interval of time—copied here. I am sure you will all agree that this must be changed. I am glad to believe that the manufacturers have realised this and are making every effort to alter it. Especially since the war they have been combining together to raise the status of the English trade, but I am glad to think that for the last ten or fifteen years we have begun to wake up and to regain our old position. In order to do this we must have the co-operation of the musical profession. Let me give you an extract from an American Consular report on the trade in Russia. He says: "The music teachers, as well as the piano dealers and tuners, are principally Germans, and they invariably recommend German instruments and earn a liberal commission thereby. According to a former professor of the Moscow Conservatory of Music, the profits on German pianos are 40 to 100 per cent." I believe a great deal of this was true of England before the war. It is well known that singers and artists found it paid to adopt foreign names, and a prejudice had been equally created largely by the means I have just referred to in favour of the German piano. This must be broken down. We want the musicians to examine the modern English pianos without prejudice, and to help the makers by definite helpful constructive criticism, and by recognising and approving, at least as cordially in a home product as in a foreign one, merit when it exists.

One factor which has helped to give the English piano a bad name, is the limited musical training of the average buyer. The great majority of people are quite ignorant of the musical value of a piano, and there is thus every inducement to supply them with the instrument on which the greatest profit can be made. Many export merchants, asked by their clients to supply a piano, have yielded to the same temptation, so that a type of piano, which is little more than a case with tricks, has been made and sold in great numbers. Many of these have found their way abroad, to the discredit of the British piano as a whole. It has therefore been proposed that powers should be obtained to lay down some minimum standard that should be attained before a piano may be exported. Such a scheme would insist on the use of good and properly seasoned timber, that the several parts be well made, especially the back, wrest plank, soundboard, and iron frame. The keys, actions, case, and finish should also reach certain standards. Whether this scheme will be adopted remains to be seen, but the fact that it has been even suggested is worth noting. Such a scheme would enable the conscientious makers and

dealers—who, I am satisfied, are still in the great majority—to trade on fair terms.

Another scheme which aims at the same result was very ably put forward by Mr. Dow, at the Congress of the Music Trades at the Midland Hotel in July last. He suggested that every piano which reached a standard to be agreed upon should be entitled to have appended to it a label, just as gold and silver are given a hall-mark. A small charge for this label was proposed, which would, even on a basis of half-a-crown per piano, bring in a fair income. He proposed to use this income to provide an office and clerical staff for the use of the trade, to assist in marketing the British piano abroad, for a benevolent fund, for research work, and for prizes. This was approved, and the council was asked to prepare a scheme to be submitted to a general meeting of the makers.

The suggestion seems to me one with great possibilities. It has two initial difficulties to encounter in opposite directions. The firms who have made their reputation by consistently supplying a sound instrument do not need the label, and feel that it would allow firms who have not in the past been careful about the quality of their materials and workmanship to reap where they have not sown; and of course the firms making the poor quality piano it is attacking may be expected to oppose it quietly but none the less strenuously. The latter opposition need not be feared, and I hope that, by some modification of the scheme, it may be possible for the well-known firms who are, of course, in sympathy with the objects to be attained, to come into the scheme, as it is obvious that without them it is foredoomed to failure. I should like to see the half-a-crown made into five shillings, as I am sure that the income, if rightly used, would repay the trade a hundredfold.

Another scheme the manufacturers have been considering is the standardisation of the piano. Ever since the invention of the steam engine there has been an increasing tendency to substitute the machine for the man in the production of wealth, and by this substitution in agriculture, and in industry, the necessities of life, food, clothing, etc., can now be produced with a fraction of the labour that was required at the beginning of the century, and the surplus labour set free has become available for the production of articles of luxury. The working hours have also been able to be reduced, and will no doubt continue to be shortened as time goes on. This tendency is one which will probably become effective at an increasing rate after the war, when fierce competition will ensue for the trade of the world, and only those nations which, by the utilisation of every improvement in the means of production, are able to sell their articles at the lowest price, will necessarily and rightly gain the ascendency in this commercial war. Thus, unless we are prepared so to standardise our manufacture that our pianos of each quality can be made mainly by machinery, we shall not be able to hold our position. This, of course, applies so far as the construction and mechanism are concerned, for it must be remembered that the piano is not a mere piece of furniture nor yet a machine; it is a musical instrument, and there is still what I might call the soul of the piano to be retained. Here the human element comes in, and the accumulated experience of our makers must be utilised and developed with the aid of science in the production of a correct design and in the final perfection of the tone of the instrument; but in the actual constructional work—in the making of the frame, the back, the action, and the case, machinery must be utilised to the fullest possible extent. It is sometimes supposed that a hand-made article is essentially better than a machine-made one. This is a fallacy which the war has proved in the case of our engineering trades, and which I venture to say competition will prove after the war in all trades where machinery can be employed—amongst them the piano industry. As a rule, wood-working machinery has been badly made, and the results obtained have, therefore, not been satisfactory; but if wood-working machines are as well made as engineering machines, and if the tools are kept perfectly sharp and run at a sufficiently high speed, beautiful results can be obtained. To employ machinery economically standardisation is essential, and firms must be prepared to co-operate with one another. Our English manufacturers almost universally have been too ready to make every variety of article. Grands and uprights, cheap and expensive, are made by almost every firm. There is no reason why there should not be a variety in unessential parts—in the case, for instance—but manufacture that is to compete in the future successfully will have to be on a large scale. The smaller firms can only achieve this by combining together, using central factories to manufacture the essential parts, and themselves assembling, finishing, and regulating them.

Any such factory should be designed for an output of at least one thousand per week, and

the workmanship even of the lowest grade piano must be of very much higher grade than it has been in the past. This necessitates thoroughly efficient up-to-date machines, well made, and with suitable arrangements for keeping them in first-class condition. For this an amply equipped tool-room is essential. In particular, cutting tools must be kept absolutely sharp, and the American practice of sharpening all tools in one central tool-shop should be adopted. Much more attention should be paid in the design of wood-working machines to improving the facility with which the tools may be sharpened. I would suggest, for instance, that, as far as possible, the tools should be mounted on standard Morse-taper spindles, as in the modern engineering milling machine, so that the spindle may fit any machine, and that the whole spindle may be withdrawn with its cutters and sent to the tool-room, where it can be sharpened and set to a gauge. A sufficient supply of cutters should be available, so that the machine-minder could at once be able to replace one if the edges are blunt. All work should be done to gauge, so that assembling may be carried out without any hand-fitting being necessary. Firms on war work will understand what this means.

Still another experiment, which is already in being, is a most interesting one. I refer to the apprenticeship scheme. Owing to the foresight and pertinacity of a few of their number, who realised the importance of a better type of foreman and workman in the factory, and who urged this matter upon the general body of the trade at the annual conferences of the association, the British piano manufacturers have been the first of any of our great industries to organise themselves for both commercial and educational purposes, and the apprenticeship scheme which they have evolved will always stand as a pioneer scheme, which is already being imitated in a greater or lesser degree by other industries, and has aroused a good deal of interest amongst educationalists. Every apprentice under this scheme is taught the general scientific principles, and a general outline of the practical manufacture of the piano throughout, at the Northern Polytechnic, which is situated at or near the centre of gravity of the trade in London. Each apprentice during the first year of his apprenticeship, spends half the week at the school and the other half at the works. During the other four years of the apprenticeship he spends one whole day a week at the school. The curriculum at the school includes mathematics, English, science—especially mechanics and sound—geometry, and trade work. Each group of boys in the second year begins the actual construction of a piano, and it is hoped that this piano will be completed during the course. Thus they will have a practical acquaintance with every operation involved in its manufacture, and if there are among them any inventive ones or any with special ability, they will have the requisite groundwork, both theoretical and practical, to equip them to improve the instrument. Even if there are none of these among them, they must surely make more intelligent and therefore more valuable workmen, and they should rise to positions of responsibility, when they will amply repay the cost and trouble of their training. I have very great faith in such a training. I believe it is far more likely to be successful than the old apprenticeship system, under which a boy was put with a man, picked almost at haphazard, to learn his trade. When it is remembered how few men know why they do any process in a particular way, and how still more infrequent is the man who can explain intelligently why he does it, it is almost wonderful that a boy learnt anything at all. They very often really did learn very little beyond the mere mechanical handling of the tools. But at a school the teachers are specially selected, the courses are carefully thought out so that every task shall teach something, and the boy is not merely making himself useful. Thus the large amount he should, and I may say does, learn, even in the small proportion of the time he spends at the school is easily accounted for. I have watched the results in the case of the building trade scholars of the London County Council, and have no hesitation in saying that at the end of the three years' full-time course which their scholarship provides, they are far and away better than boys who have spent the same time as ordinary apprentices. Unfortunately the war is interrupting all this work at present.

In still another way the piano manufacturers are endeavouring to make up for lost time, and to put their work on a sure foundation. I allude to the establishment of a school of research in connection with the piano. They have guaranteed an income in the first instance for three years to enable this to be carried on, and the Industrial Research Committee is supplementing it. It is naturally almost impossible at present to obtain men with the necessary qualifications to carry on the work, but as soon

as they are released from war work great progress is to be expected. The field is a very extensive one; it is almost untrodden up to the present, and, no doubt, as work proceeds, it will open up new vistas for experimental investigation as all research work does. I hope that great and important results may come from this work.

Up to the present, in the manufacture of the piano, practice is far in advance of theory, and there are almost innumerable things which have been found desirable in practice for which every maker who has adopted them gives a different reason—possibly not the correct one in any case. It is these things which must be investigated. Then when we know why something needs to be done, and how a certain effect results, we may be able intelligently to improve the design and to raise the construction of the piano to a higher level. This is our hope, and if we all work together, and pool our knowledge and experience, I feel sure we can realise our ambition once more to bring back the time when Britain shall once again lead the way in the piano industry.

In addition to what I have said above on the industrial side of the pianoforte history, a great deal might be said on its æsthetic aspect. Much credit is due to those manufacturers who have been for years as "men crying in the wilderness," and who, despite lack of encouragement, have steadily persevered with their endeavours to improve the tonal value of their instruments. The developments which I have been speaking about are undoubtedly due almost entirely to their efforts. I know they have encountered a large amount of inertia, and it is only by great enthusiasm, and faith in the possibility of raising the industry to its old premier position, that they have attained the success for which all credit should be given to them. I have even heard a story that there was a time when a manufacturer being approached with the remark, "I understand you are a piano maker," replied, "You are quite wrong, my friend; I do not make pianos, I make money." I trust that any such attitude is rapidly becoming impossible, if it is not already a thing of the past.

It is a fact that must never be forgotten, that every piano produced in this country—especially if it is exported—is either helping to raise or lower the reputation of the British piano; and it is up to every manufacturer to see that he, at least, is not going to help to lower the standard; and we are very hopeful that the scheme which I have outlined may result in everyone connected with the industry, in whatever capacity, regaining the pride of craftsmanship which resulted in the foundation of the old Guilds, and that every maker, foreman, or workman, will set this high ideal before him.

There is another point. Whether it is true or not that a country gets the government it deserves, it is certain every public gets the piano it deserves; and the fact that there is a ready sale for an imperfect instrument shows clearly that a low standard of musical taste is prevalent. If we can raise the quality of the public taste, we shall ensure a larger demand for the best type of instrument.

I am glad to think that there are great hopes that the rising generation may possess a much keener appreciation of good music than their fathers. The American teachers who lately visited this country were surprised at the quality of the singing which they heard in our elementary schools. They stated that it surpassed anything they had heard in any other country, and I see that in the new Education Bill Mr. Fisher is desirous of further encouraging the teaching of music and singing in our schools. We must not be content with this. There is only one solution—there must be a combination of one and all. Musicians, composers, publishers, manufacturers, and teachers must work together, and must no longer be content to realise their own personal ambitions. For this reason I am very glad that you, Sir Frederick, have honoured me by presiding here to-day, and that I have been able to lay before you some of the difficulties and aims of the manufacturers, and I feel sure that we may confidently look to you for your co-operation. We should be most grateful to you if you would aid us by your influence and advice in bringing about a much closer co-operation and more intimate connection between the leaders and members of the musical profession in England and the productive side, who probably constitute the greater part of my audience this afternoon. Such an alliance, which I trust we may see realised in the near future, cannot fail to have great and far-reaching results, industrially, commercially, and educationally.

DISCUSSION.

THE CHAIRMAN (Sir Frederick Bridge, C.V.O., Mus.Doc.), in opening the discussion, said that he, in common with all musicians, desired to do all he could to aid in improving the musical taste and musical appreciation of this country, and to restore her former supremacy in the pianoforte industry.

With regard to the first point, people with musical taste and knowledge would not be content to put up with a poor instrument, and the increase of that taste and knowledge among the people of this country would do much to promote the production of better instruments. With reference to the second point, the Germans could not be blamed for having had the shrewdness and audacity to take possession of the British market, but he hoped that after the war everybody in the musical profession would do his utmost to see that German goods were kept out of this country, and that the supremacy of the British pianoforte industry was restored. It was true that when the "Twelve Apostles," as they were called, came to this country from Germany in 1760, they were welcomed and encouraged, and they did much to develop the pianoforte, but since then English makers, such as Wornum, Broadwood and Collard, had contributed inventions of extraordinary value, of which this country had lost the benefit. The author had mentioned that British firms had been content to retain old-fashioned actions when abroad the inventions made by Englishmen were universally used. Personally he believed that during the first three parts of the last century the pianoforte makers of this country could not be accused of such slackness, but during the last part of that century they began to lose their energy, to trust to the reputation they had already gained, and to be indifferent to the necessity of competing with the instruments that were being made abroad. The pianofortes made in this country in the early part of the nineteenth century were as good as they could possibly be. At the present time he had in his possession a little piano bought by his father when he (Sir Frederick) was a boy in the choir at Rochester Cathedral. When his father died he had the case renovated and the piano itself overhauled, and he still used it daily, and as he had been at Westminster Abbey for forty-three years, and had used the piano a great deal during all that time the instrument must have been very well made. He did not think some of the modern pianos would last so long if they were subjected to the same amount of use. With regard to the use of machinery in the manufacture of pianos, he had no doubt that the most minute perfection could be obtained in that way, and he agreed with the author that all the tools used should be sent to a central tool-house to be kept in perfect order by a man who understood the work. He thought the statement made by Dr. Lardner, and quoted in the paper, that it was impossible for a man to influence the tone of the piano by the way in which he touched the keys, could hardly be justified at the present time. He thoroughly supported the great movement of having boys apprenticed to the pianoforte business, which was a very important matter, and one in which the Musicians' Company might be able to help.

Major J. Mackenzie Rogan, M.V.O. (Bandmaster of the Coldstream Guards), said that when he went to India about forty years ago it was very difficult to get pianos of any kind there, most of those that were obtainable being old instruments of English make, whilst a few were imported from Germany. He made up his mind then that when he could afford to buy a piano it should be a British one, because when he joined the Service two-thirds of the bandmasters in the British Army were German civilians and the majority of them treated the bandsmen in the true Prussian spirit. The British musician at that time had no chance, and it was the British public that was to blame for that, just as he thought the British public was now to blame for not giving sufficient encouragement to the British pianoforte manufacturer, to the British composer, and to British music in general. The bandmaster of the regiment he joined as a boy was a very fine musician, but he was thought nothing of because he was an Englishman; whilst on the other hand a German street musician was in one case sent to an unsuspecting regiment abroad as a gem of the first water. Some years ago, when he returned to England on leave, he bought a piano from an English firm and took it back to India with him, where he had it in use for about seven years, keeping it at high pitch on the plains, where sometimes the temperature reached 110 or 112 degrees in the summer. When he left India that piano was almost as good as when he bought it, and he sold it to a dealer in India for more than the price he originally gave for it. All the pianoforte tuners that he met in India were Germans, who were out to "do the Britisher down," and he had had personal experience of a case where a German tuner had deliberately interfered with the mechanism of an English piano which he had been called in to tune. He thought that the bandmasters of the British Army could do as much as most men to advance the British pianoforte industry, because they travelled all over the world with their regiments and could give their advice to people in India, Africa, Burma, and all the other places to which they went. British officers were more disposed now to listen to the advice of bandmasters than they were thirty or forty years ago, because they realised that the British bandmasters could more than hold their own. He was glad to say that there was not a single foreign bandmaster in the British Army at the present time.

Mr. John Collard said there was no doubt that British pianoforte makers would not accept all that had been said about them at the meeting. He did not admit that they had been asleep for a number of years, but thought that for a long time they had made the very best and most reliable instruments that could be manufactured, although it was quite true that they did not always adopt the changes that were introduced on the Continent. He himself had been actively associated with the industry for fifty years, and during the whole of that time his firm had done all they could to turn out good work in as large a quantity as possible, and he

believed that was true of all the other pianoforte manufacturers in this country who had a reputation to sustain. At one time they were very seriously handicapped by German competition, but during all that time there was thoroughly good and reliable work being done amongst British manufacturers. If people would not be so willing to take goods that came from abroad, but would stand by British goods, they would find that British pianoforte manufacturers would supply them with instruments that would be a credit to them as makers and advantageous to the public who purchased them.

MR. JOHN D. CHALLEN supported Mr. Collard in denying that British pianoforte manufacturers had been wanting in energy during the period, say, from 1880 to 1900. In the year 1885 his firm sent to the Melbourne Exhibition up-to-date pianofortes built with iron frames and over-strung, and they received the highest number of points on the jury list for those instruments. At that time his firm was sending thirty pianos a month to Melbourne, and one would have thought that their success at the Melbourne Exhibition would have sustained and improved their reputation; but from that date their trade decreased to zero, owing to German competition. The German manufacturers sent over a very large number of instruments in ships subsidised by the German Government, the manufacturers themselves being assisted by banking facilities, and those pianos were dumped upon the market and offered to dealers in large quantities. The dealers had to buy them to protect themselves, because when they refused the Germans threatened to put the pianos into the auction room, with the result that the market would be flooded with them. Those German methods of penetration accounted in a great measure for the British manufacturers having lost their hold on the Colonial markets. The same thing had happened in this country also, but we had learned our lesson now. If measures were taken to strengthen the home market, and to establish the industry on a firm foundation, British pianoforte manufacturers had the ability and the enterprise to enable them to hold their own in a fair field. He very much valued the establishment of the Research Department, of which the author was the distinguished head. It marked an era in the history of the pianoforte industry that now a trained scientist had come forward to inquire into matters which the practical man in the workshop was incapable of investigating. The author was looking at the manufacturing side of the industry on the one hand and at the distributing side on the other, and on the distributing side he looked forward to getting the support of the musical man. There was no doubt that that support ought to be obtained. Before the war musicians favoured German instruments, but he did not think they would do so in the future, and British manufacturers ought to do all they could to produce the best possible instruments.

MR. JAMES A. MURDOCH (President of the Pianoforte Manufacturers' Association) said he thought too much had been heard at the meeting about the past, and too little about the future. It was important for the British pianoforte manufacturers to gain the support of the musical profession, and he was pleased to see present two distinguished members of that profession—the Chairman and Major Rogan. He agreed with the latter as to the influence of the British Army bandmasters who went to all parts of the world, and was interested to hear of Major Rogan's experiences in India, from which country he had recently received a very interesting and gratifying report. He thought the British industry could look forward hopefully to the future, and a meeting such as the present one gave the Pianoforte Manufacturers' Association every encouragement to go on with the programme they had already outlined.

On the proposition of the CHAIRMAN, seconded by Mr. T. DYSON, a hearty vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

ENGINEERING NOTES.

The Centenary of the Institution of Civil Engineers.—A milestone in the history of the profession has been marked by the centenary celebration on January 2nd last. The avocation is commonly, but mistakenly, called civil in contradistinction to various other callings, such as mechanical, marine, mining, electrical, gas or other similar occupations. The charter does not recognise these distinctions, and excepts only the term military engineers from the list of the corporate members of that body, and, moreover, the history of the proceedings amply justifies that exclusion. It is remarkable that in the charter of the Institution which describes the profession, that of the railway engineer is not included. A trial by locomotives on rails by Trevethick was made in 1808, nine years before the date of the charter, and the first public railway was opened seven years later. But the first beginnings of the locomotive were made about sixty years earlier, and many experiments were made in the course of the eighteenth century. Surely the promoters of the Institution were strangely cautious to object to the introduction of the steam locomotive, which to-day is universal over the continents of the world.

By-product Coking.—Mr. G. B. Walker, in his recent paper before the Institution of Civil Engineers, points out that the war having stimulated the demand for hydrocarbon explosives, these are now commandeered by the Government, the coking plant necessary for recovery of the explosives being under the control of the Ministry of Munitions. Although the principle of external heating of the retort oven, as originally introduced by Evence Coppée, remains the same, considerable

modifications in detail have been gradually introduced by various builders as the result of experience. The object of these modifications has been chiefly to increase the rapidity of the coking process by the application of more intense heat, and by the heating of the air for combustion; convenience and economy in operation have also received much attention. The recovery of by-products has been greatly developed, and in particular many experiments, with more or less success, have been made for achieving the "direct" recovery of sulphate of ammonia. One of the most important developments has been the utilisation of the surplus gases in internal engines, and for town illumination, metallurgical furnaces, and other manufacturing purposes. Mr. Walker describes the principal features of half a dozen of the most successful types of oven in use in this country, and the recovery plants associated with them, and cited figures showing the economics obtained by the "direct" recovery of sulphate of ammonia, here and in Germany. He also compares the relative value of the surplus gases used in producing steam (utilised through turbines) and in internal-combustion engines, to the advantage of the latter.

Concrete Shipbuilding.—We have referred to this subject in our number of October 12th last, and revert to it in the following extract from *Concrete*. The first British-built concrete motor launch has now taken the water. This vessel has dimensions 23 ft. by 5 ft. 3 in., by 14 in. draught, and is of the fast estuary type. The method of construction has been a special one, the concrete shell being only $\frac{5}{8}$ in. thick. Of a larger character is a motor coaster 92 ft. 4 in. by 19 ft. by 19 ft. by 10 ft. draught, a boat about to be laid down in a British yard, which will have a motor winch, the usual raised quarter-deck and forecastle, a large hold, hatchway, and engine aft. America is going one better than this by building a concrete ocean-going vessel about 300 ft. long, with a cargo capacity of 4,500 tons. The shell of the hull is 6 in. thick, and will weigh less than a wooden hull for the same cargo capacity. Only ninety days will be required to build the first vessel of the type; soon it is expected to build the hulls in two months, or in even less than that time. Reinforced concrete has several advantages over the steel and wood hulls, one being durability, as apparently, provided that the vessel is well designed and carefully constructed, the greater the age the stronger she gets; in fact, at about twenty years' old she should be in very much better condition, so far as strength and tightness are concerned, than a new vessel built of steel, or the famous old iron hulls.

British Engineering Extension in China.—Mr. A. Rose, C.I.E., H.M. Commercial Attaché at Shanghai, delivered a lecture lately to the London Chamber of Commerce on "The Prospects of British Extension in China." He said that there can be no doubt that China offers a wonderful field for many forms of engineering enterprise, for textile machinery in the cotton-growing districts, for electric light and power plants, for pumps, motors, and all the machinery and accessories which are essential to industrial enterprise both on land and on the water. At present there are only 87 electrical installations in operation in China. The Germans secured a large number of these contracts in consequence of their co-operative system, which enabled one central institution to quote for and supply complete installations, and, if necessary, to finance them. He had never made a journey into the interior without receiving constant inquiries for machinery of all sorts, but the Chinese know little of the scope and possibilities of mechanical power. They need careful education as to the machinery which can be useful to them, as to where they can obtain it, what it will cost, what profit it will make, and how they can manage to pay for it. Such information can only be supplied by men who are especially trained for the work, and who can devote their whole time to it. Our young practical engineers seem to have the knack of winning the confidence of the Chinese, and all that we need is more men of that type in the field.

Victorian Coal.—In a recent speech, Mr. Livingstone, Minister of Mines, Victoria, is reported to have said that in the very near future the brown coal industry would be one of the greatest in Victoria. When the deposit at Morwell was properly opened up this State would be independent of Wonthaggi and Newcastle. Besides the coal in the open cut, it was estimated that 100 ft. below there were 13,000,000 tons of coal. He was waiting for the reports of electrical engineers, and if they were what he expected, the Government would be recommended to transmit power from Morwell, which would run nearly all the machinery in Melbourne, and at a cheaper rate than water could produce it.

Indian Superheater Locomotives.—The results obtained with superheater engines in India fully justify the decision come to by many railway administrations that all engines for main line work should be fitted with superheaters. The last Indian Railway Board report gives an instance of a superheater engine (2–8–0 type) which was tried for several months on the heavy grades (1 in 25) between Sibi and Quetta on the North-Western Railway, with most satisfactory results, showing a saving in fuel of nearly 30 per cent., as compared with saturated engines of the same class, and handling the same loads with much greater ease. The use of superheater engines is also extending to 2 ft. 6 in. gauge lines, which were supplied by the North British Locomotive Company and are equipped with the Robinson superheater.

GENERAL NOTE.

THE RARER MINERALS IN THE BRITISH EMPIRE.—In a lecture before the London School of Economics on November 16th, 1917, Mr. Sydney Johnstone, of the Scientific and Technical Research Department of the Imperial Institute, pointed out that almost all the rarer key-metals can be obtained within the British Empire. Tungsten is obtainable from Burma (now the most important producing centre in the world), Queensland and elsewhere, and the Empire provides 35 per cent. of the world production. The metal is also now being extracted successfully in the United Kingdom. Molybdenum is another metal which the Empire produces in adequate supply. Both are of great value for special armament steels and for high-speed tools. The monazite deposits in Travancore and Ceylon are the richest in thoria known, and contain abundant supplies of ceria, the other chief rare earth required for incandescent mantles. Ferrocerium, an alloy of iron and cerium, has useful applications for pyrophoric automatic lighters, and has been employed for tracing the flight of shells. Practically the only valuable key-metal which the Empire can only produce at present in very small quantities is platinum. It was suggested, however, that much larger quantities of this might be obtained in certain metallurgical workings in Canada, from which platinum, palladium and other rare metals could be derived as a by-product.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

JANUARY 23. — ALEXANDER NEWLANDS, M.Inst.C.E., Chief Engineer, Highland Railway, "Water Power in Great Britain (with special reference to Scotland): its Amount and Economic Value." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

JANUARY 30.—SIR WILLIAM GEORGE WATSON, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." SIR ARTHUR D. STEEL-MAITLAND, Bt., M.P., will preside.

FEBRUARY 6.—WM. FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

FEBRUARY 13.—LORD LEVERHULME, "The Relations between Capital and Labour — Reasonable Hours, Co-partnership, and Efficiency." W. A. APPLETON, C.B.E., Secretary of the General Federation of Trade Unions, will preside.

FEBRUARY 20.—MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." SIR ASTON WEBB, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

FEBRUARY 27.—SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

MARCH 6. — A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 20. — FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

Dates to be hereafter announced :—

MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. LAWRENCE BALL, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

FEBRUARY 14. — SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India." The RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 14.—

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

February 5.—C. du Plessis Chiappini, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

March 5.—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

Charles R. Darling, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

Syllabus.

Lecture I.—January 21.—*Methods of Producing High Temperatures.* Special fuel furnaces—Oxy-hydrogen flame—Oxy-acetylene—Thermit—Electric furnaces.

Lecture II.—January 28.—*High Temperature Processes.* Smelting of platinum and metals of high melting-points—Welding and cutting by oxy-acetylene flame and electric arc—Thermit welding—Production of steel and other metals by electric furnaces—Fixation of atmospheric nitrogen—Metal spraying.

Lecture III.—February 4.—*Products and their Uses.* Artificial graphite for various purposes—Carborundum for abrasion and refractory purposes—Alundum and silica for chemical apparatus and refractories—Calcium carbide for making acetylene—Pure metals by thermit processes—Siloxicon and other silicon—Carbon compounds for refractories and thermal insulators—Aloxite and its uses.

Edgar Crammond, Secretary of the Liverpool Stock Exchange, "The Economic Condition of the United Kingdom before the War: The Real Cost of the War: and Economic Reconstruction." Three Lectures.

February 18, 25, March 4.

J. Young, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

Cobb Lectures.

Professor Henry R. Procter, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

Monday, January 21...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. C. R. Darling, "High Temperature Processes and Products." (Lecture I.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. Canon J. O. Hannay, "The Church and the Army." (Part II.)

Geographical Society, Kensington Gore, S.W., 5 p.m. Mr. W. J. Harding King, "Study of a Dune Belt."

Engineers, Cleveland Institute of, Corporation-road, Middlesbrough, 7.30 p.m.

Tuesday, January 22...Engineers, Junior Institution of, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. F. W. Lanchester, "Industrial Economics, during and after the War."

Royal Institution, Albemarle-street, W., 3 p.m. Professor W. M. Flinders Petrie, "Palestine and Mesopotamia." (Lecture II.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Mr. F. Reeves, "Rail-Creep." 2. Mr. H. P. Miles, "Creep of Rails."

Wednesday, January 23...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. A. Newlands, "Water Power in Great Britain (with special reference to Scotland): its Amount and Economic Value."

Geological Society, Burlington House, W., 5.30 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor E. W. Hope, "Some Constructive Suggestions in regard to the proposed Ministry of Health."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m.

Japan Society, 20, Hanover-square, W., 3.30 p.m. Mr. T. Khori, "Japanese Drama."

Thursday, January 24...Royal Society, Burlington House, W., 4.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor S. Wilkinson, "Generalship—a Campaign of Napoleon's (1808)." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Major D. C. Campbell, "Flying and Photography."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. F. G. C. Baldwin, "Telephone Exchange Transfers and their Organisation."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. F. A. W. Phillips, "British Trade and the Metric System."

China Society, School of Oriental Studies, Finsbury-circus, E.C., 3.30 p.m. Mr. M. F. A. Fraser, "Annals and Anecdotes of Jengiz Khan."

Friday, January 25...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor J. S. Townsend, "The Motion of Electrons in Gases."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture II.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, January 26... Royal Institution, Albemarle-street, W., 3 p.m. Professor W. J. Pope, "The Chemical Action of Light." (Lecture II.)

Offer of a Set of Journals.—A set of unbound *Journals*, in good condition, extending from 1902 to 1909, and from 1910 to 1915, has been placed at the disposal of the Secretary of the Royal Society of Arts for presentation to a public library or institution which will undertake to bind and preserve them. The Society is willing to add a bound volume for 1909–10. Applications should be addressed to the Secretary, Royal Society of Arts, John Street, Adelphi, W.C. (2)

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes in the City of Westminster.—January 18, 1918.

No. 3401. JANUARY 25, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Journal of the Royal Society of Arts.

No. 3,401. VOL. LXVI.

FRIDAY, JANUARY 25, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, JANUARY 28th, at 4.30 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." (Lecture II.)

A demonstration of oxy-acetylene welding and cutting will be given.

WEDNESDAY, JANUARY 30th, at 4.30 p.m. (Ordinary Meeting.) SIR WILLIAM GEORGE WATSON, Bt., Chairman of the Maypole Dairy Company, "The Manufacture of Margarine in Great Britain." SIR ARTHUR D. STEEL-MAITLAND, Bt., M.P., will preside.

Further particulars of the Society's meetings were published in the last issue of the *Journal*.

CANTOR LECTURE.

On Monday afternoon, January 21st, Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, delivered the first lecture of his course on "High Temperature Processes and Products."

The lectures will be published in the *Journal* during the summer recess.

PRESENTATION OF THE SOCIETY'S ALBERT MEDAL TO MR. ORVILLE WRIGHT.

A report has just been received of the ceremony held at Memorial Hall, Dayton, Ohio, on October 27th, when Lord Northcliffe presented the Society's Albert Medal to Mr. Orville Wright. Dayton is the birthplace and home of the Wright family; it was here that the brothers Wright conducted their principal experiments in aviation, and it is now a large and rapidly-growing centre of aeroplane manufacture.

Lord Northcliffe said that when he heard from His Royal Highness the Duke of Connaught that it was the desire of the Royal Society of Arts to award their Albert Medal to Mr. Orville Wright, he eagerly accepted the suggestion of the British Ambassador at Washington that he should proceed to Dayton and make the presentation. Wilbur and Orville Wright were the first persons to ascend from earth in a mechanically-propelled airplane. To them, and to them only, was due the credit. Moreover, they were the real inventors of the means of controlling all airplanes.

What the two brothers had done for aviation was generally being realised throughout the world. Without aviation it would at the outset have been impossible for the British to defend themselves on their line in France and Flanders against the great guns which the Germans had been preparing for forty years. By means of this invention they were able to locate those guns and put them out of action. The British nation was therefore grateful to the Wrights for enabling them to be provided with a machine that carried them over the period when they were building their great guns.

That the Germans should have misused this machine, that they should delight in dropping bombs upon the poorer parts of our great cities, and on our seaside resorts, and that they should take pleasure in killing women and children, was not the fault of the inventors of this machine, for the Germans turned every scientific invention to the purpose of war. As for ourselves, we regarded the invention of the Wrights as the means of protection of our island against possible future wars. We believed that the airplane would enable us, with our comparatively small population, to defend ourselves against any future combination of the Central Powers of Europe. Lord Northcliffe also expressed the belief that the work going on at Dayton to-day, the work which he had seen that morning, would help to bring this horrible war to a conclusion.

PROCEEDINGS OF THE SOCIETY.

SEVENTH ORDINARY MEETING.

WEDNESDAY, JANUARY 23rd, 1918; SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Balston, Reginald M., London.
Beamish, Richard H., D.L., Cork, Ireland.
Beckett, Joseph Edge, London.
Dawson, Charles Williamson, London.
Dewar, James M., London.
Dyson, Sir Charles Frederick, J.P., Windsor.
Jack, Henry Joseph, North Wales.
Livingstone-Learmonth, Thomas Livingstone, London.
Love, Charles William Grosse, London.
McKnight, William Archibald, Chile, South America.
Miller, Hans Eric, London.
Sowrey, Major John, R.F.C., Newmarket.
Woodward, William Harrison, Farnham, Surrey.

The following candidates were balloted for and duly elected Fellows of the Society:—

Anderson, Gilbert, London.
Attwater, Richard, Preston.
Baroda State, The Minister of Education, Baroda, India.
Boote, Edgar M., Coventry.
Bradshaw, Granville E., Walton-on-Thames.
Chadwick, David Thomas, I.C.S., Beckenham, Kent.
Coatalen, Louis, Wolverhampton.
Diamant, A. St. John, L.R.I.B.A., Egypt.
Forster, Martin O., D.Sc., Ph.D., F.R.S., London.
Lo Tian Cheok, The Hon., British North Borneo.
Mastin, John, D.Sc., Litt.D., Kenyon.
Mort, George Frederick, London.
Pegler, Frank, Retford.
Sempill, Wing-Commander the Master of, R.N.A.S., London.
Ware, Alfred George, Bournemouth.
Willis, Thomas Wilkinson, Sheffield.

The paper read was—

WATER POWER IN GREAT BRITAIN (WITH SPECIAL REFERENCE TO SCOTLAND): ITS AMOUNT AND ECONOMIC VALUE.

By ALEXANDER NEWLANDS, M.Inst.C.E.,
Engineer-in-Chief, Highland Railway.

The situation created by the war has immensely intensified our interest in all questions affecting our social and economic existence, which it is sometimes said we shall have to construct anew on the conclusion of peace. This belief, at the present time, finds expression in the general trend of public opinion towards a desire for investigation and research. It may be said that waste in any form is now abhorred, and that economy has become our watchword. In particular, the former waste and abuse of our natural resources is being keenly inquired into, and evidence of this is found in the important and far-reaching proposals towards national reconstruction which are contained in the Report of the Coal Conservation Sub-Committee of the Ministry of Reconstruction.

The legislative aspect of the problem considered by the Sub-Committee is being investigated by a Committee appointed by the Board of Trade, the end in view being to "ensure that there shall be an adequate and economical supply of electric power for all classes of consumers in the United Kingdom, particularly industries which depend upon a cheap supply of power for their development."

The Sub-Committee proposes to supply all industries with electrical power generated at big super-power stations, not more than sixteen in number for the whole country, and to eliminate or combine all smaller stations. The primary object of the scheme is to economise our coal supplies by a national scheme of electrification. Fifty-five million tons of coal out of 80,000,000 used in the United Kingdom for the production of coal could be saved. This, with the saving of by-products now wasted, would effect a saving of millions of pounds. An increase in the use of power is of the highest importance to the future prosperity of the country.

The development of electricity has been hindered by the excessive number and smallness of electrical undertakings. At present the supply of electricity in Great Britain is split up among six hundred companies and municipal undertakings. The reform proposed by the Committee is to supersede small undertakings by laying down throughout Great Britain a network of trunk lines to be fed by these sixteen "super-power stations." Generating machinery should be of 20,000 h.p., and in important industrial districts of 50,000 h.p. By-products might be extracted from coal before it is used for the production of power, and various electro-chemical processes which are essential for this country should be carried on near by. Sites for stations must be outside towns. The power authorities will be controlled by a National Board of Electricity Commissioners. Existing plants will be handed over on equitable terms to the new authority.

The value and importance of such an investi-

gation cannot be doubted, and, as bearing upon the subject, it is interesting to read the report of Mr. Wilson Fox, M.P., Hon. Secretary of the Empire Resources Development Committee, at a recent meeting at the Aldwych Club, when he said that by centralisation of power supply, and the careful conservation of by-products, as well as by the sale of power, a saving to the State of £100,000,000 per annum could be effected. This would represent a reduction of 2*s.* 6*d.* per £1 in the income tax. It should be noted that centralisation of power supply, with proper transmission, is the negation of centralisation of industry.

Coal has ever been, and will probably continue to be, our principal source of power, but in considering the question of power it is sometimes forgotten that one cubic foot of water per second falling eleven feet will give one horse-power in any modern turbine, and no investigation into the power resources of the country is complete that does not include water power within its scope.

The continued non-utilisation of the water power of these islands is an economic waste. In the census of production report for 1907 we find that the total power of industrial engines in Great Britain and Ireland is 10,578,485 h.p.; road rollers and road locomotives owned by public authorities, 167,192 h.p. Of these industrial engines, steam reciprocating engines represent 9,118,818 h.p.; steam turbines, 530,892 h.p.; internal-combustion engines, oil, gas, etc., 680,177 h.p.; and water power, 177,907 h.p., or 1·6 per cent. of the total. It is computed that 2,500,000 h.p. is employed in the production of electrical energy.

General Considerations.

In considering to what extent water power could contribute to our total power requirements, several important considerations have to be kept in view. For instance, when we draw from our coal supply for power we are drawing from a source which is not inexhaustible. The late Sir William Ramsay estimated that, at the wasteful rate at which we were using up our coal supplies in 1911, we might look for their complete exhaustion in a period which he estimated at 175 years, and long ere that time coal would be scarce and dear. In 1907 we raised 6 tons of coal per head of population as against 3½ tons in Belgium, and 2½ tons in Germany. It is much to be desired, therefore, that the aspirations of the Sub-Committee should speedily materialise. Sir Dugald Clerk considers that our fuel needs could possibly be met by the economical use of one-half of the coal we now use, and advocates a more extended use of water power.

Atmospheric precipitation in the form of rain or snow is the source of all our supply of water. This rainfall gravitates into lakes, rivers, and subsoil areas, according to the physical and geological character of the country on which it falls, and it is chiefly by the impounding and control of it that it can be utilised for power production.

It is, however, sometimes forgotten by enthusiasts on the subject of water power that all rainfall cannot be set aside for their requirements. Rainfall is primarily required for domestic water-supply. Industrial and manufacturing interests, as well as supply for canals and for navigation and fishing in certain of our rivers, must be provided for, as must also agriculture. Agriculture is peculiarly dependent upon surface rainfall in proper season, but over and above the surface supply it is estimated, in the "Water Powers of Canada," that in the upper 100 ft. of the earth's surface there is stored sufficient water to form a lake 17 ft. deep, or a total equal to about seven years' rainfall. In times of drought this underground storage is drawn upon to some extent, and chiefly by capillary action by the plant life on the surface.

We may infer, therefore, that in pervious areas the unrestricted abstraction of subsoil water by pumping or deep drainage may have as injurious an effect on agriculture as would the diversion of the surface rainfall for power purposes.

Meteorologists are practically agreed that continuous records for about thirty years are desirable in arriving at reliable figures of "average" rainfall in any country. For the thirty years, 1870–1899, Dr. Mill has worked out the following average figures for the British Isles:—

	Area.	Average Rainfall.
	Square miles	Inches.
England	50,053	31·62 say 32
Wales	7,376	49·53 „ 50
Isle of Man . .	224	34·66 „ 36
Scotland . . .	27,413	46·85 „ 47
Ireland	32,694	42·28 „ 42

or an average for the British Isles of 39 in.

It will be recognised that without a close scrutiny into the distribution of this rainfall, "average" figures for a country as a whole cannot be made much use of by investigators of water power possibilities, but, fortunately, Dr. Mill goes minutely into this question of distribution. All rainfall, therefore, cannot be utilised for power, and the question of the amount of it which can be so used is a very complex one.

Rivers.

In many countries the natural flow of great rivers is available for vast power possibilities. Comparatively few of our largest British rivers are, however, so reliable and uniform in their daily discharge as to render even a reasonable proportion of the total rainfall they deal with available for power.

Moreover, it is chiefly in the relatively short length of their upper reaches that the largest English rivers have any considerable fall. Except near their source many of them have a fall of not more than one or two feet per mile, and are tidal and navigable for long distances inland. On the other hand, there are large rivers, such as the Dee, Spey, Findhorn, Conon, in regions like the Scottish Highlands, which have a fall of fourteen and sixteen feet per mile near their mouths, and on many smaller ones the fall is very much greater. An excellent feature of several of the great Irish rivers is that they have a very considerable fall almost at the point where they discharge into the sea.

River discharge, as affected by rainfall, is primarily dependent upon the slope or inclination of the catchment area, although the geological character of the area, the average temperature, the presence or absence of agriculture and afforestation, enter into the question. The following examples, from Stevenson's "Canal and River Engineering," illustrate the variation n flow which exists in rivers in different parts of the country, and the hopelessness of arriving at any accurate general deductions from them:—

	Surface slope inches per mile.	Cub. ft. per min. per square mile.
Boyne	—	257
Clyde	$1\frac{1}{3}$	65
Conon	(Rapid River)	19·9
Forth	11	75·7
Foyle	$1\frac{1}{4}$	28·6
Ribble (before works)	47·8	159
Tay (before works)	2 to 9	120
Wear	16	22
Thames	1 to 20	20·4

The rainfall in the catchment areas is not given. In arriving at general conclusions for purposes of power investigation, what detracts from the value of these figures, apart from the want of uniformity in them, is that they are evidently deduced from gaugings taken near the mouths of the rivers. The discharge per square mile given practically represents, therefore, the total discharge divided by the entire drainage area, much of which is subject to a low rainfall, and is open, flat, permeable country.

Beardmore's Hydraulic Tables give ordinary summer discharges of various rivers, streams and springs, as uninfluenced by any immediate rains. The geological formation of the catchment areas is also given. The results vary in an extraordinary manner—viz., from 2·4 cubic ft. per minute per square mile in a chalk area to 400 cubic ft. per minute per square mile, this latter being the winter discharge off a felspar formation.

It will be seen, therefore, that river discharges vary within a very wide range, but it may be presumed that, speaking in general terms, short rivers with a rapid fall give a much less ordinary discharge than long sluggish rivers, the obvious reason being that the rapid river runs off its heavy rainfall in floods. Moreover, the catchment areas drained by these rapid rivers are, as a general rule, of a mountainous, bare, and impervious character, where little percolation or saturation can take place.

It is interesting in this connection to note that it is already becoming observable in the Scottish Highlands that the rapid deforestation of the country for national purposes is having the effect of increasing the number of floods and the volume of flood discharge in that part of the country. The cutting of shallow open drains for improving the hill pasturage for sheep grazing was previously observed to have had the same effect.

In "Canal and River Engineering" the following ratios of ordinary to flood discharge are given:—

Thames	1 to	5·9
Erin	1 ,,	3·9
Clyde	1 ,,	4
Tay	1 ,,	3·4
Conon	1 ,,	27·2
Ganges	1 ,,	2·4
Irrawaddy	1 ,,	10
Mississippi	1 ,,	1·9
Nile	1 ,,	9·5

The figures are given with reserve, and, I think, rightly so, as especially for short, rapid

rivers the difference between low summer flow and maximum autumn flood is greater than that given.

The following figures regarding the River Ness, abstracted from a report by the late Mr. Bateman in 1870, are of value, as they deal with the characteristics of a river draining one of the wettest and most mountainous regions in the British Isles. The Ness is only seven miles in length. It flows out of Loch Ness, which has a drainage area of 683·3 square miles, an area of 13,940 acres, or 21·8 square miles, and is twenty-four miles long by an average of one mile wide. Its elevation is 50 ft. above Ordnance Datum. A very large loch such as this almost certainly acts as a regulator, and has a considerable effect upon the river discharge. Mr. Bateman estimated the ordinary flow of the river at 250 cubic ft. per second, and the flood discharge during two memorable floods in 1834 and 1849 at 29,000 and 52,000 cubic ft. per second respectively, the ratio of ordinary to flood discharge being for the 1834 flood 1 to 116, and for the 1849 flood 1 to 208. The same ratio for the Conon, already noted, is 1 to 27·2, and the ordinary flow of these rivers works out at 20 cubic ft. per minute per square mile in the case of the Conon, and 22 cubic ft. in the case of the Ness. From the "Investigation of Rivers" report it would appear that the summer flow of the Severn—a typical large English river —is about 28 cubic ft. That of the Derwent is 11·1 cubic ft., the flow in winter flood being 452 times greater.

Twenty cubic ft. per minute per square mile is probably a rough approximation of the summer flow of our short rapid rivers.

All the foregoing figures must be received with caution. There is much valuable evidence on the subject on record, and much good work is daily being done, but there is such a want of uniformity in the matter of units used in recording results that the whole subject becomes somewhat bewildering. For instance, "ordinary" flow is too indefinite to corelate with either "minimum or "average" flow, although in perusing the text in various authorities one is led to think they are intended to mean the same thing. "Flood discharge" is too indefinite, as floods vary within a wide range. It is much to be desired that the flow of rivers and yield of catchment areas could all be put on record in definite standard units.

The investigation of the water power possibilities of any particular area involves a very large amount of study and labour, and, unfortunately, the results arrived at may be practically valueless if applied even to an adjoining area.

Each catchment area is a problem in itself, and it is extremely difficult to generalise upon the power possibilities of a whole country even with approximate accuracy.

SCOTLAND.

Power by Impounding.

Scotland, and in particular the Scottish Highlands, being the country north of the Forth and Clyde, possesses more water power possibilities than any other part of Great Britain This part of Scotland is the most extensive mountainous region in the British Isles, and it has within it, as a whole, the highest rainfall. the only localities comparable with it as regards rainfall being Seathwaite in Cumberland and Snowdon in Wales. An annual rainfall of 160 in. has been recorded on Ben Nevis; 182 in. in Cumberland: and 193 in. on Snowdon.

Over a considerable extent of this northern area of Scotland the rainfall exceeds 60 in. per annum. and it is fairly uniform throughout the year. On the west coast particularly the climate is humid and moist, and there is comparatively little loss due to evaporation, and geologically the area belongs to the older primitive rock formations, so that little percolation takes place. The country is, however, bare, largely uncultivated and treeless, so that much of the rainfall is meantime lost in flooding in the rivers.

From the water power standpoint, the fine, natural lochs, many of them of large area, and at very considerable elevation, are of extreme value. They act as regulators to the rivers in dealing with the discharge of abnormal rainfall, and, in many cases, are ready to hand for regulation and control as power dams. The Highland area under review extends to, approximately, 12,000 square miles, and the seaboard surrounding it is extremely indented and extraordinarily developed, long sea lochs running far inland, affording excellent facilities and shelter for shipping. No part of it is more than twenty miles from the sea or the Caledonian Canal.

There is no melting of snow throughout the summer months to augment the natural flow of the rivers, as in Switzerland, Norway, and Sweden; but, on the other hand, the fine equable climate renders interruption of power plants by snow and ice in the winter improbable.

It is in a country such as this that one looks for possibilities of power in bulk.

Generally speaking, the highest land has the

highest rainfall, and the Scottish Highlands is the largest and most uniform tract of country approaching and exceeding 3,000 ft. in height to be found in Great Britain. Calculating from Bacon's Map of Average Rainfall, prepared by Dr. Mill, I find that there is in Scotland, and chiefly in the Scottish Highlands, 11,500 square miles of country, or 42 per cent. of the total area, having a rainfall of 50 in. and over.

The following table admits of comparison with the rest of Great Britain :—

estimate of the water power available in Scotland by the impounding of the discharge from the loch basins. For this purpose I have assumed an average rainfall of 42 in. This as an average rainfall is, of course, exceeded over more than half the area of Scotland. Moreover, the records of rainfall are obtained from gauges that, as a rule, are situated at lower levels rather than at the higher elevations where rainfall is greatest. In any case it is usually impossible to impound all the rainfall which would flow to the sea ; and,

AREAS HAVING 50 INCHES OF RAINFALL AND OVER.

	Total Area.	50-inch area.	Percentage of Total Area.	Location.
	Square miles.	Square miles.		
Scotland	27,413	11,575	42 per cent.	Scottish Highlands and Southern Uplands.
England	50,053	3,360	6·7 ,,	Lake and Shap Districts and Devon & Cornwall.
Wales	7,376	3,390	46 ,,	Entire Central area.
Ireland	32,694	5,910	18 ,,	Chiefly Donegal, Connemara, Killarney.

It may be noted that in the Scottish Highlands the 40-in. average rainfall line scarcely gets east of the Highland Railway, notwithstanding that the great Grampian range of mountains is situated there. The explanation is that the rain clouds blowing in from the Atlantic discharge their rain on striking the mountainous region to the west of the Grampians.

The Bathymetrical Survey of the Scottish Fresh Water Lochs is of the greatest assistance to anyone interested in the water power possibilities of Scotland. I venture to say that this great work of Sir John Murray and Mr. Lawrence Pullar will yet be appreciated as it deserves to be. Nothing of the same kind has been done for the rest of Great Britain so far as I can learn, except the similar and equally valuable work by Dr. Mill for the English Lake District, and that by Professor Jehu for Wales.

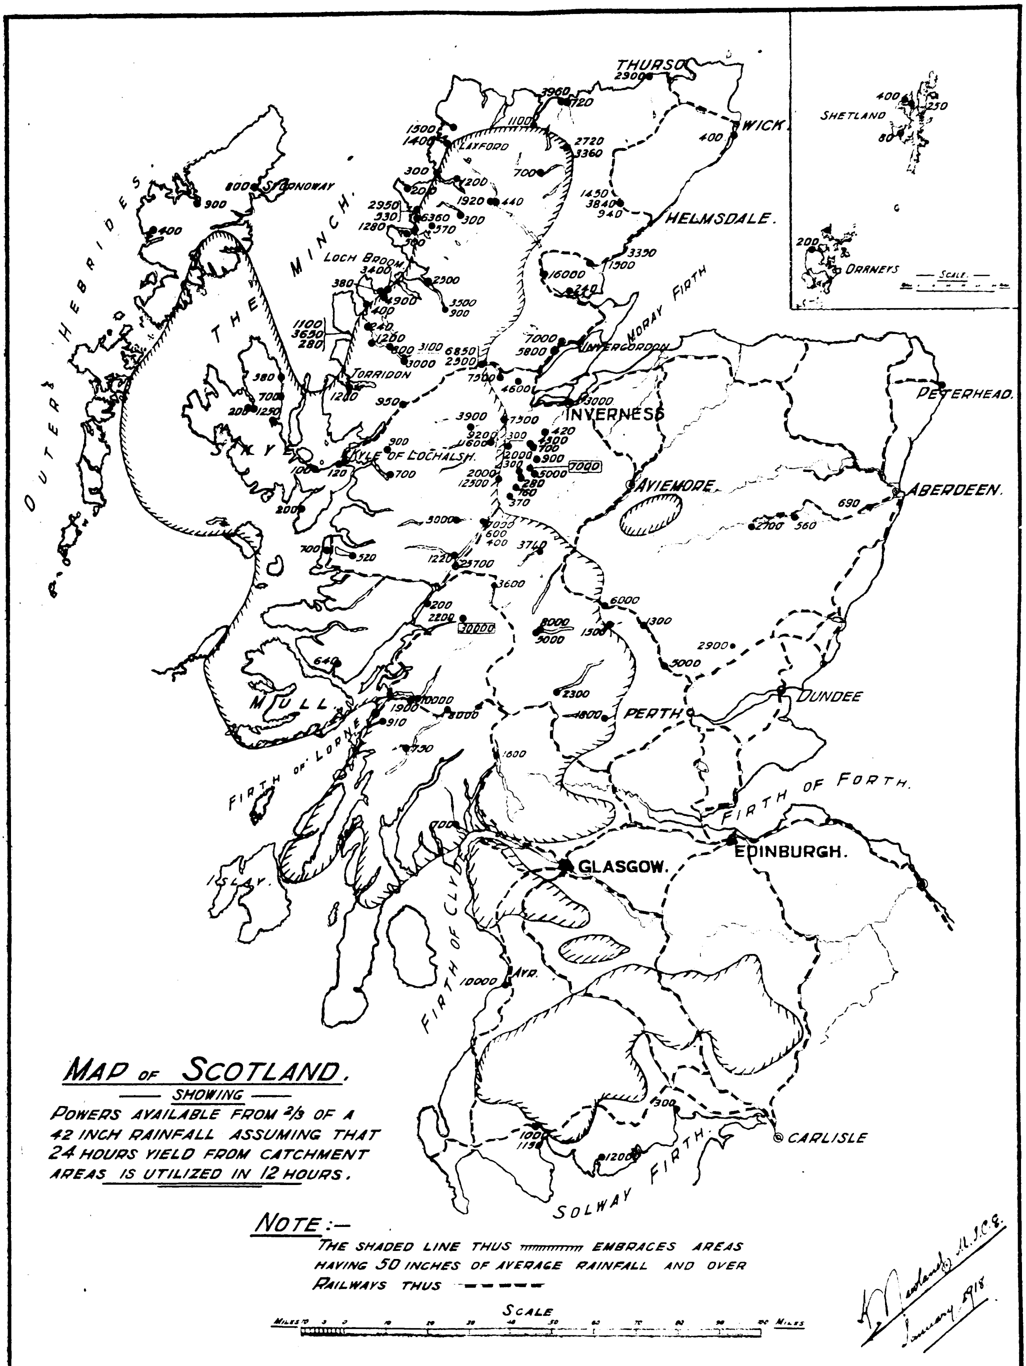
It is much to be desired that a bathymetric survey of the inland waters of the remainder of Great Britain should be put in hand, and in view of the importance and value of such a survey it should be undertaken either by the Ordnance Survey Department or the Hydrographic Department of the Admiralty, and not be left to the zeal and public spirit of private individuals.

With the information available in the Bathymetrical Survey, and the use of contoured maps, I have endeavoured to arrive at an approximate further, it is desirable to arrive at figures which will understate rather than exaggerate the ultimate power possibilities. A final reason for adopting a 42-in. rainfall is that, if uniformly discharged, it represents a yield from catchment areas of 3 cubic ft. a second per square mile, and this is a very convenient figure for approximate calculation.

Drainage areas have been taken from the Bathymetrical Survey referred to. In every case a loch has been selected for regulation and control as an intake, and the drainage area of it taken as the catchment available, although manifestly in the case of a long open conduit, leading to a pressure pipe, additional water could be intercepted.

The fall available has been reckoned as that from the intake to the nearest point on the seaboard, or on the route of the Caledonian Canal, or nearest line of railway, these being the localities where industrial works would most readily be laid down.

Of the 42-in. rainfall it is assumed that two-thirds, or 28 in., is available for power, and the figures on the accompanying map represent the power available, assuming that the flow for twenty-four hours is utilised in twelve hours, the efficiency of the machinery being reckoned at 75 per cent. It will be noted that 14 in. of the assumed 42 in. have been deducted. This, and any surplus over 42 in., is therefore reserved



for evaporation and absorption, and for compensation to rivers.

If, as previously suggested, the summer flow of rivers in mountainous districts be 20 cubic ft. per minute per square mile, equal to $4\frac{1}{2}$ in. of rainfall, a total of 14 in. would maintain three times the summer flow in these rivers, but evaporation and absorption would have to be met by the rainfall in excess of 42 in.

It may be argued that evaporation and absorption are not sufficiently provided for, and probably this is so, but it may be assumed that

some part of the rainfall lost by absorption is eventually recovered; and as regards evaporation this is not excessive in regions such as we are considering, where the rainfall is fairly regular and the climate moist and humid. The usual allowance for evaporation—12 in. to 16 in. of rainfall per annum—may, therefore, be excessive in this case. As regards compensation to rivers, from one-quarter to one-third of the total rainfall is considered liberal. In Scotland the latter figure has almost become standard, it having been awarded by arbitration to the River Tweed—a famous salmon river—from the Talla drainage area when it was impounded for the supply of domestic water to Edinburgh.

If our previous deductions as to the ordinary flow of rivers be correct, such an amount of compensation water would maintain about three times the summer flow in a river, but abnormal flooding would be checked, and while floods at inopportune times destroy spawning beds they, on the other hand, have a cleansing effect on the alveus of a river, and it is for salmon-fishers to say whether their general effect is for good or evil.

Along with the map, I have given, in an appendix at the end of this paper, the data from which the powers have been calculated. It must be distinctly understood, however, that the map, the data referred to, and the method of calculating the powers, are simply an attempt to deal in a general manner with the possibilities of water power existing in the country and to arrive at an approximate estimate of the amount of such powers. For instance, it may be that certain of the powers given must be rejected on the score of expense in development. On the other hand, no allowance has been made in the estimate for possible additions to the drainage areas of the lochs by diversion and collecting works, nor for any special storage such as would give increased powers for, say, 100-day periods, as well as increased head.

The powers on the map total up to 375,000 h.p. in round figures. By diversion and linking-up of adjoining catchment areas, and by impounding beyond the extent provided for in preparing the estimate, it may be assumed that, for, say, 100 days' supply, 650,000 h.p. is available. This is based on what has been done at Kinlochleven. By our formula the power from the 55 square miles of drainage area would be 17,500 h.p., whereas we are told that it is equal to 30,000 h.p. for 100 days.

The Clyde, Forth, and Tweed basins have not been dealt with, owing to the important water-supply and other interests already involved nor have the power possibilities of rivers and small streams been included.

The over-all cost of development per horse-power cannot manifestly be generalised upon.

Existing and Other Attractive Powers.

In the Scottish Highlands the largest installations so far laid down is the Kinlochleven works of the British Aluminium Company.

The drainage area is the relatively small one of 55 square miles, but it has no natural reservoir within it, so that the expense of constructing a dam of a maximum height of 86 ft. and of a length of 1,037 yards had to be faced.

The area had, however, the paramount advantage of a high elevation, the overflow cill of the dam being 1,065 ft. above Ordnance Datum, the effective head being 920 ft. It has a further advantage in respect of its high rainfall of fully 70 in. per annum, and, by the terms of purchase, the water rights were bought outright, so that no compensation to the river has to be provided for.

The reservoir, probably the largest artificial one in Europe, has a length of 7½ miles, and an average width of about half a mile. It impounds about 20,000 million gallons of water, sufficient to give an output of 30,000 h.p. for about one hundred days. The cost of the works proper was £600,000, or £20 per horse-power.

In 1909 Mr. Morrison, manager of the company, stated that the output of the plant was 150,000,000 units per annum, and he compared this with the annual requirements of the London County Council, 97,000,000 units; and of Glasgow, for trams and lighting, 63,000,000 units.

The requirements for electric traction in the United Kingdom for 1909 were 253,000,000 units.

After allowing for interest on capital and depreciation, the total cost of the current was one-sixteenth of a penny per unit, and he hoped it would ultimately be one-twentieth of a penny. This figure is, of course, arrived at on a load factor almost approaching unity. One-sixteenth of a penny per unit is, approximately, 34*s.* per horse-power per annum continuous working.

It is interesting to note that in this case all the water had to be artificially impounded, whereas, in many cases, the existing lochs could be advantageously utilised.

The feature of the Kinlochleven scheme is the excellent fall available. If the method adopted in arriving at the powers shown on our map be applied to this area, the power available would be about 17,500 h.p. Having developed the

power in the Leven basin the company are now asking Parliamentary authority to utilise the Laggan basin. The same company has also 7,000 h.p. installed at Foyers on Loch Ness.

As an example of a small installation, that at Raven's, near Strathpeffer, may be instanced. The water is drawn from a small dam costing little more than an ordinary farm mill-dam, and on a head of 600 ft. develops 120 h.p., and supplies current for lighting and power to Dingwall and Strathpeffer.

There are installations at Stanley, Blair Castle, Loch Rosque, Achnasheen, Evanton Village, Ardross Castle, Fochabers, North Esk, and elsewhere.

Attractive possibilities exist in the stretch of the Caledonian Canal between Loch Ness and Inverness. Loch Ness drains approximately 700 square miles, and the level of it is 50 ft. on Ordnance Datum. The stretch of the Canal referred to is the same level as the loch, and by drawing from it such a quantity of water as would not interfere with navigation, 3,000 h.p. for the working days of the year could be got at Inverness.

Another attractive area is that drained into Loch Luichart near Strathpeffer. The loch drains 149 square miles of very wet country, and has an area of 1,150 acres. The river flows out of the loch in a series of cascades, and falls 125 ft. in a length of 850 yards. Two-thirds of a 42-in. rainfall would, under these conditions, represent 6,000 h.p. on a twelve-hour day basis. The outlet of the loch is a narrow rocky gorge, and impounding could be easily and cheaply carried out.

The possibilities of Lochs Morie and Glass, on the east shoulder of Ben Wyvis, are worth investigation. These lochs are at elevations of 621 ft. and 712 ft. respectively, and the combined powers from them, if developed on the shore of the Cromarty Firth, amount to 12,800 h.p.

The elevated area—approximately 1,500 ft.—between Glen Moriston and Glen Urquhart on Loch Ness is also worth looking into.

Power from Rivers.

Although we have so far been considering the development of power in bulk by utilisation of the impounded waters from large, elevated drainage areas with heavy rainfall, there are considerable and widely distributed possibilities of power development in many rivers and small streams all over the country.

What strikes one in moving about the country is the number of small water power sites now long abandoned.

In the economic development of a country these small powers are well worthy of consideration.

Previous to the invention of the steam engine, about 1790, the only sources of power were water and wind; but the potentialities of steam rapidly drove these humble competitors from the field. The inception and growth of railways as a means of transport also assisted in this. Railways linked up the principal centres of population and carried coal there cheaply, and so established them as centres of industrial development, and rural industry was strangled.

The use of water power in the growth of the great industries of the English northern counties is referred to by Mr. Edwin A. Pratt, in "History of Inland Transport." He writes:—

"The textile industries originally established in the eastern counties by refugees from the Netherlands and France afterwards spread through the southern and western counties, attaining in each district to a very considerable growth long before they were of any importance in those northern counties with which they were afterwards mainly to be associated. The migration to the north occurred at a time when the woollen industries were paramount and the cotton industries had still to attain their subsequent stupendous growth. It occurred, also, long before the Aire and Calder were made navigable, so that, in this case, we cannot say the industrial centres already mentioned as being situated on or near to those two Yorkshire rivers were set up there, as the towns on the River Severn had mainly been, in order to secure the convenience of river transport.

"The chief reason why the bleak and barren moorlands of the north were preferred to the fair and fertile plains of the south for the further expansion of these great national industries was that, in the days when the steam engine of James Watt was as yet far off, the heavier rainfall in the English Highlands of the north and north-west, together with the more numerous streams pouring down mountain-sides both of greater height and greater extent than in the south, gave to the clothmakers, not only the abundant water-supply they wanted, but also the particular kind of motive power, through the use of water-wheels, on which they then mainly relied for the working of their machinery.

"It was in the interests of this power derived from falling water that the textile industries first migrated from the eastern counties—where the

streams flow but slowly, and from comparatively slight elevations—to the western counties, where there are streams coming from hills of from 800 to 1,000 ft. in height. These, for a time, answered better the desired purpose, though only to be more or less discarded in turn for northern or north-western streams which, with a greater rainfall, had their rise on heights of from 1,500–2,000 ft. and were so numerous that almost every one of the small manufacturers who set up business for himself on the otherwise cheerless slope of a Yorkshire hillside, could have a brook, rivulet, or a mountain torrent of his own, or at least make abundant use of one before it passed on to serve the purposes of his neighbour.

"In alluding to the woollen trade as affected by these conditions, Dr. Aikin remarks, in his 'Description of the Country from Thirty to Forty Miles round Manchester' (1795): 'It would seem as if a hilly country was particularly adapted to it, since it almost ceases where Yorkshire descends into the plain'; though the position has, of course, been entirely changed by the general resort to steam in preference to water power.

"Other industries, besides those relating to textiles, whether woollen or, at a later period, cotton, took advantage of the same favourable conditions as shown in the case of Sheffield, where the earliest of the cutlers who were to make Hallamshire goods famous throughout the world, settled down at the confluence of the Sheaf and Don because those streams afforded them the best available means of operating their tilt-hammers."

The development of small powers from suitable streams is a relatively simple and inexpensive matter. In the case of large rivers, however, it is difficult economically to utilise even a considerable part of the normal flow owing to the cost of devising a cheap scheme for dealing with a large volume of water on the low fall normally available. It has been stated that turbines, for a head of 25 ft., cost £4 per horse-power, as against £1 per horse-power for a head of 500 ft. A high fall is the ruling factor in all economically developed power schemes.

The extraordinary variation in the flow of rivers has been already illustrated, and if it be assumed that 20 cubic ft. per minute per square mile be available for power this represents ·03 h.p. per foot of fall. A river like the Spey, draining 1,100 square miles, would, therefore, represent on a 15 ft. fall, requiring about a mile of power water flume, 500 h.p. On many reaches of such a river where the fall is much greater and the drainage area less, the power available would, however, be much greater, owing to impounding being possible. On certain large Irish rivers it has been calculated that 50 cubic ft. per minute per square mile is available for power, but in any scheme involving the use of such a quantity of water it may be assumed that a considerable fall is available. Dr. Mill, in one of his publications, gives the drainage areas of certain Scotch rivers as under:—

River.	Sq. Miles.
Tweed	1642
North and South Esk	683
Dee	816
Don	512
Deveron	599
Spey	1148
Ayr.	223
Dee (Kirkcudbright)	386
Annan	374
Esk	381

Attention was recently directed to the steepness of the gradients of northern Scottish rivers, in consequence of a statement by Mr. Alexander Ross, past-President of the Institute of Civil Engineers, who, in a presidential address, advocated the drainage of the Spey meadows, and said that the Spey was probably the most rapid river in Scotland.

This directed attention to other rivers, and some controversy took place, as the result of which Mr. C. H. Roberts, Aberdeen, claimed for the Aberdeenshire Dee the distinction attributed to the Spey, while Mr. Jenkins, Aberdeen, claimed it for the Findhorn.

These gentlemen published particulars on these gradients, which are worth reproduction (see p. 177). Mr. Jenkins says the Don is industrially the most useful river in Scotland.

Owing to the difficulty in arriving at total powers available directly from river flow, I have not shown anything derivable from this source on the map, which shows power obtainable from impounded areas only.

Economic Value.

The powers shown on the map total up to 375,000 h.p., and it is believed they are arrived at on a conservative basis. Assuming that these powers are looked upon as a national asset, the development of them to their maximum efficiency should be carried out under statutory control.

Unless this be done, the perpetual right to

them will be absorbed by private enterprise, and so be lost for all time to the nation. It does not follow that private enterprise should not be encouraged to develop the powers, but this could be done under statutory authority whereby it would be possible for the State to acquire the powers if and when it required them for national purposes, or to buy them up altogether under a pre-arranged basis of purchase, in the same manner as at the inception of the railway movement the Government retained an overriding interest in all railways.

Such a control could, moreover, ensure that by generating current of the same periodicity at every power station the whole of them could be made to feed into a network of transmission lines. In this way abnormal rainfall in areas widely apart could be converted into power and not be lost.

In Canada the preservation of water rights has been legislated for in a very thorough manner. In "Water Powers of Canada" an estimate, which is really a "hazard" in the absence of reliable information, places the power available as 17,000,000 h.p.

The amount developed in 1911 in the ten provinces was as under, the figures for Ontario Province, which controls the Niagara Scheme and the Ottawa River, and which is the largest consumer, being shown within brackets:—

	Horse-power.
Electrical Energy	742,955
Ontario	(400,683)
Paper and Pulp	158,051
Ontario	(57,575)
Other industries	115,515
Ontario	(74,008)
Totals.	1,016,521
Ontario	(532,266)

Speaking with respect to Ontario's possibilities on April 19th, 1905, Premier Whitney said: "The water power of Niagara shall be as free as air, and more than that, I say on behalf of the Government that the water powers all over this country shall not in future be made the sport and prey of capitalists, and shall not be treated as anything but a valuable asset of the people of Ontario whose trustees the Government of this people are."

These powers in Ontario are now to be had under statutory leases, granted under the seal of the Lieutenant-Governor.

Of a list of twenty-four leases granted since 1898, nine are for ten years and fifteen for twenty years, a typical rental for a twenty years' lease for 2,000 h.p. being, per horse-power, first and second years, $10; then 50 cents per horse-power; minimum payment, $1,000.

At the expiry of the lease the lands, buildings and powers, revert to the Crown, together with dams, weirs, tunnels, races, flumes, sluices, pits, and other structures, the lessees being at liberty to remove the machinery, there being a proviso that where buildings and structures are of a permanent character and necessary for useful and proper development the Lieutenant-Governor may, on the advice of the Hydro-Electric Commission, purchase them.

The Ministry of Reconstruction Sub-Committee recommend sixteen stations of normally 20,000 h.p., or a total of 320,000 h.p., say 400,000 h.p.—about what is shown on the map.

If carried any great distance the Scottish powers would have to be reduced to, say, 60 per cent. efficiency to allow for conversion and transmission losses, but even then their total would amount to 300,000 h.p.

Mr. Archibald Page, Glasgow, has given the power requirements of Scotland at end of 1916 as under:—

	Horse-power.
Municipal and Company-owned—actual load	263,000
(Capital cost, £47 per kilowat on a plant capacity of 221,000 kilowats.)	
Privately-owned electric plants	219,000
Direct driving by steam and gas engines	637,000
Total	1,119,000

It would appear, therefore, that there is sufficient water power in the Scottish Highlands to meet a large part of the demands of industrial and municipal requirements in Scotland, but, on the other hand, it is doubtful if the cost after development and transmission to existing industrial areas would be less than the cost of power generated there at the pit-head. It may be, therefore, that the sphere of usefulness of these water powers is the region in which they are available, along with a fringe of the adjacent territory to which they could be transmitted. This, however, is probably one of the most interesting features of Scottish water power. It exists in a territory destitute of coal, and it is due to the presence of, or accessibility to, cheap coal that the great centres of industrial activity are located where they are. It may be said that shipping facilities also determined their location, but such facilities exist all over the northern half of Scotland. If it be true, therefore, that our industrial growth was due to cheap coal for the steam engine, it is equally true that activity centred round the main shaft of the engine because power transmission to any distance was, from a steam source, both tremendously expensive and wasteful. The simplicity with which electrical energy can be transmitted and applied by means of multiple driving has changed all this, and decentralisation of industry has become possible. But is decentralisation desirable? What is the situation as we find it to-day?

When the long-looked-for day of peace arrives, it may be found that Great Britain is a debtor nation to as great an extent as in pre-war days we were a creditor nation, and strenuous effort, much of it in new directions, will be required of us industrially in the future. The demands of labour for the administration and control of industry become increasingly insistent as the war goes on, and this and the position of women as industrial workers, as well as improved housing, are questions which will require far-reaching and meantime indeterminate adjustments when our economic life is resumed on the conclusion of peace.

The extent to which we have neglected the agricultural possibilities of our country is also causing anxiety to reflective minds. We were quite content in times of peace and plenty to grow 1,500,000 tons of wheat and to import 5,500,000 tons, and few of us ever contemplated an existence under which the Russian and Rumanian wheat crop would not be available for our needs, and when even our food supply from America and our Colonies can only reach us by a trade route infested by pirates.

Even before the war emigration and depopulation of our rural districts, with a corresponding augmentation of our city populations, was a disturbing consideration, and efforts were made to show that what was the Mother Country's loss was our Colonies' gain, and that, therefore, the balance was maintained.

It was argued for instance, as a comforting thought, that from 1861 to 1911 the population of Greater London had increased by almost exactly 4,000,000. In that year—1911—the population was 7,251,000, almost exactly that of Canada, fully one and a half times that of Australia, and more than seven times that of New Zealand.

The increased population in all the larger towns varied to some extent, but was a feature of them all, and, as a matter of fact, we were told that only 22 per cent. of the people of Great Britain and Ireland lived under rural conditions. The fact that a nation's wealth consists in a healthy, contented peasantry was lost sight of, and the race was being allowed to degenerate in the fœtid vortex of industrial life in great cities. Moreover, we were content to make up any loss due to emigration by the utilisation of an influx of alien peoples that was beginning to flow in unrestrictedly.

Much of this condition of things is attributable to the centralisation of industry, which has absorbed our rural population to an increasing extent year by year.

The slump in agriculture and the strangulation of rural industry made existence for a rural population impossible, and employment in industrial centres, or emigration, were the only alternatives.

Now we have the cry of "back to the land," and a demand for afforestation, which latter undoubtedly offers vast and far-reaching remedial possibilities. Both of these schemes should, however, as far as possible be associated with an industrial development, and where water power exists this is eminently practicable. Moreover, it will be surprising if the broadcast distribution of electrical energy adumbrated by the Coal Conservation Committee does not have the effect of gradually extending the borders of the present congested industrial centres, thus rendering possible better housing conditions and a more attractive environment for the workers, the want of which is at the bottom of much of the industrial unrest we read of.

But if this eventually be possible within the area of activity to be served by the sixteen super-generating steam-driven stations, what of the coalless territory beyond the range of these? Such territory must either resort to water power, if it exists within its borders, or, industrially, it must become derelict.

North of a line drawn from the Firth of Tay to the Firth of Clyde lies about 66 per cent. of the total area of Scotland, that is to say, 18,000 square miles out of a total of 27,400. The population in this region, excluding Perth and Dundee, is approximately 1,100,000, or only 23 per cent. of Scotland's total. The Highland peoples in this northern area have passed through many vicissitudes since the feudal days when they did nothing but fight each other, but their capacity to fight and endure, either in doing their share of the world's work in times of peace, or for the defence of liberty, as at the present time, is yet unimpaired.

It is in territory such as this that a keen discriminating intellect is developed, and that the brawn and muscle of the British race is bred and reared, and not in congested hives of industry, and if employment can be found for such a people in their home environment it is all to the nation's interest to provide it.

The great bulk of the northern population is located in the towns and villages on both shores of the Moray Firth, from Peterhead on the one hand to Wick on the other. The "Laigh of Moray" eastwards, and also Easter Ross, are two of the richest agricultural districts in Scotland.

If we are to witness the birth of an industrial-cum-agricultural era in this part of the country, it follows that sufficient Highland water power must be conserved for the purpose. Objection is sometimes made to a plea for industrial development in rural districts, by contending that such districts lie beyond the range of raw material supply. Such objection overlooks the fact that much of our finer industrial output requires little raw material. Its value lies in the workmanship put into it and not on the weight of it. It is sold per unit and not per ton. The Consolidated Tool Company of Great Britain laid down their works at Peterhead, the Arrol Johnston Motor Company migrated from Glasgow to Dumfries, and the large business of the "K" Boot Company is located at Kendal.

Apart also from experiments in intensive agriculture such as are now being carried on in Hereford, farming operations generally could well participate in the broadcast distribution of electricity for lighting and power for all the multitudinous operations carried on in the field and in the farm buildings.

The real advantage of combining industry with agriculture on any scheme of land settlement is that the industrial employment supplements the living on the croft or small holding, which of itself will not provide a sufficiently remunerative and attractive livelihood.

Dr. Scott, Professor of Political Economy, Glasgow, in a report to the Scottish Board of Agriculture, strongly advocates the initiation of a scheme of home industries using power in the Highlands.

The working up of wool, timber, hides, peat, building materials, sandstone, limestone, granite, marble, slate, etc., is work which can be entered upon at any time, and in the Memoirs of the Geological Survey on Mineral Resources of Great Britain, we read of the deposits of pegmatite, or "graphic granite," which exists in Sutherlandshire, and from the felspar in which, equal to 72·5 per cent. of the whole, potash can be extracted. Between Lochs Laxford and Inchard it is estimated that 190,800 tons of pegmatite is available. Further deposits exist at Durness and Eribol, and at Overscaig on Loch Shin. The residue from potash felspar can be used as a fertiliser, and as a glaze in pottery, enamel and electric ware and other purposes.

Since writing the foregoing I observe that Mr. E. A. Ashcroft, speaking at the Institution of Mining and Metallurgy, says there are in the extreme north-west of Sutherlandshire, and within reach of admirable shipping facilities, 12,000,000 tons of pegmatite in intrusive veins of a total

width of a quarter of a mile, ideally situated for open quarrying operations. He estimates that, from a plant which he specifies, 50 tons a day of 80 per cent. potassium muriate could be obtained equal to what is obtained from all the 300 blast furnaces in the country put together. These Scottish deposits would alone suffice to maintain twice such an output for fifty years at a cost not exceeding £7 a ton, and not more than £15 to £20 a ton even under war conditions.

Graphite exists more or less freely in several localities, such as Loch Carron and Loch Maree. Heddle, in his "Mineralogy of Scotland," says in Glen Strathfarrar in 1818, five tons were quarried at £13 a ton and sold for £93 a ton. It is also to be got at Invergarry, Huntly, and elsewhere. Molybdenite and chromite are also to be got, the latter being especially abundant in Shetland, where previously many thousand tons of it were obtained. Steatite exists in various localities, and the Skye diatomite, which contains 97·78 per cent. of silica after being heated to expel the water, is well known. Diatomite is also found in Tolsta Lewis, and in Mull. The iron, consisting largely of brown hematite, at Tomintoul is worth mention. It was first worked at the beginning of the eighteenth century, and contained as much as 72·72 per cent. of pure iron. The iron deposits in Raasay are now well known. Lead ore is meantime being worked at Georgemas, and barytas near Lybster, both in Caithness.

ENGLAND AND WALES.

I have purposely, in referring to Scotland, dealt with every aspect of my subject, for the reason that it is best to follow out one's argument to a conclusion, and for the further reason that what has a general bearing on the situation in Scotland applies with equal force to England and Wales and Ireland.

For purposes of loose approximate comparison, and on the assumption that one-third of all rainfall flows to the sea, I have prepared the following table:—

	Area.	Average elevation.	Total rainfall.	Horse-power.
	Sq. miles.	Feet.	Inches.	Continuous.
Scotland	27,400	450	48	1,200,000
England	50,000	250	32	900,000
Wales	7,400	450	51	350,000
Ireland	32,700	400	42	1,150,000

From the above, if the figure already arrived at for Scotland be assumed correct, on the same ratio the power for the other countries would be:—

	For 12 hours' daily supply.
England	281,000
Wales	109,000
Ireland	359,000

If based proportionally on the 50-in. rainfall areas in each country, the powers would be:—

	50-inch area.	Horse-power.
	Square miles.	
Scotland	11,575	375,000
England	3,360	108,000
Wales	3,390	109,000
Ireland	5,910	190,000

Neither of the above results can possibly be of the slightest value, although it is a striking coincidence that the resultant for Wales is the same in both of them.

There are very much greater rivers in England than in Scotland, but remarkably few lochs, which are such an outstanding feature of Scotland.

The following is a list of rivers and catchment areas from Dr. Mill's pamphlet:—

River.	Sq. miles.	River.	Sq. miles.
Solway	1,280	Southampton Water, etc.	1,052
Lune	435	Rother	411
Ribble	707	Medway	673
Mersey	1,693	Thames	5,310
Dee	843	Blackwater	425
Towy	778	Yare	1,234
Usk	594	Ouse	3,168
Wye	1,599	Nene	917
Severn	4,384	Welland	658
Lower Avon	884	Witham	1,107
Parrett	636	Trent	4,017
Taw	442	Ouse	4,187
Exe	572	Tees	809
Stour	488	Wear	464
East Avon	680	Tyne	1,130

From Mill's survey of the "English Lakes" we get the following information, and, dealing

with it in the same way as for Scotland, we arrive at the following results:—

Loch.	Height.	Drainage area.	Area of Loch.	Fall.	Horse-power.	Point of Development.
	Feet.	Sq. miles.	Sq. miles.	Feet.		
Windermere	130	88·65	5·69	110	3,300	At sea-level.
Ullswater.	476	55·95	3·44	—	—	—
Wastwater	200	18·64	1·12	180	1,100	At sea-level.
Coniston	143	23·34	1·89	120	—	—
Buttermere	329	6·50	·36 }	150	1,150	On 150-feet fall.
Crummock	321	16·80	·97 }			
Ennerdale	368	16·95	1·12	300	1,700	At sea-level.
Bassenthwaite	223	*91·51	2·06	100	3,100	On 100-feet fall.
Derwentwater	244	31·83	2·06	—	—	—
Haweswater	694	11·20	·54	200	750	On 200-feet fall.
					11,100	
				(Say	11,000)	

* Excluding Derwentwater and Thirlmere.

as is usually found in mountainous country. Careful investigation with the aid of maps would very probably disclose considerable possibilities of power by collecting and impounding the yield from adjoining areas.

The Lake District is one of England's beauty spots, and objection on æsthetic grounds might be made to any interference with the natural charm of it, but the utilisation of the lakes for power development would not, of necessity, mar the beauty of the natural features any more than did the construction of the Thirlmere Reservoir. At the same time, seeing that coal exists on the western border of the district, it does not appear likely that the English Lakes will be requisitioned for power at least for some time to come.

The reference to Thirlmere directs attention to the fact that in England the requirements for domestic water-supply obtrude themselves much more prominently than in Scotland, seeing that the density of population is much greater and the average rainfall much less.

For Wales, with the assistance of Professor Jehu's figures and one-inch maps, from which I roughly calculated a number of drainage areas, I have prepared the table given on p. 182.

The lochs dealt with are all in North Wales—in Snowdonia—and in eastern Carnarvonshire. Generally speaking, the whole of the Welsh lochs are small. Many of them are at great elevations, but, unfortunately, these, as a rule, drain very small areas. I have no particulars of the North Wales Power Company, and do not know where they generate their power. The orographical features of Wales are extremely confused, and seem to follow no sort of system such as is usually found in mountainous country.

The absence of large lochs in England and Wales, and the want of elevation in the country as a whole, severely restrict the possibilities of water power development.

The direct flow of rivers appears to be the principal source of energy available, and owing to the variation in flow, and for the other reasons stated, no great amount of power appears to be economically available.

What has been done on the Dee at Chester is an interesting and recent example of utilisation of river flow. Mr. James Gordon, who installed the plant, has given me certain particulars The Dee drains 713 square miles above Chester and by utilisation of the old Roman weir on the river there, the yield from this catchment area is passed through turbines and, judging by the units generated, appears to develop about 500 h.p. on a fall varying from 1 ft. to 9 ft.

If the average fall be called 5 ft. the power per square mile of drainage area per foot of fall $=\frac{500}{713\times5}=14$ h.p., requiring 90 cubic ft. per minute per square mile, or about four times what I suggested for the Scottish rivers. The average flow of the Dee at Chester is given as 90,540 cubic ft. per minute = 127 cubic ft. per minute per square mile, and this is said to represent 56 per cent. of the rainfall in the

Loch.	Drainage area.	Elevation (above sea).	Fall utilised.	Horse-power.	Where developed.
	Sq. miles.	Feet.	Feet.		
Lochs Gwynant and Dinas	15	175	150	770	Pant Aber Glasslyn.
Padarn and Peris	23	339	300	2,350	On Menai Straits.
Llydaw	1½	1,416	1,200	600	Llyn Gwynant.
Cwellyn	8	463	200	550	On 200-feet fall.
Ogwen	6	984	400	800	Bethesda.
Cawlyd	1½	1,164	1,100	560	Dolgarrog.
Llyniau Mymbyr	18	588	500	3,000	Bettws-y-Coed.
Eigeau	4	1,219	1,200	1,600	Porth Llwya.
Crafnant and Geirionydd	3½	616	600	700	Trefriw.
Dulyn and Melyn	1½	1,747	1,700	850	Tal-y-Bont.
Conwy	2¼	1,488	750	560	Yspytty-ffan.
	(Say	12,000)		12,340	

(Powers are calculated in the same way as the Scottish powers.)

catchment. Judging by the time-lag shown in the monthly flow and rainfall figures, the river has a very flat gradient.

IRELAND.

Like England, Ireland's possibilities of power appear to be principally in her great rivers.

The peculiar geographical feature of Ireland is that a great part of the interior of the country is a flat plateau of varying elevation, but nowhere at any great height above sea-level. In this plateau flow great sluggish rivers which have a steep fall to the sea for the last few miles of their length.

This feature of the rivers makes them extremely valuable for power production. I have read two excellent papers on Irish water power, one by Mr. Tatlow and the other by Mr. Dick, and as neither of these gentlemen, with their knowledge of the country, ventures to bring out a grand total of the powers available, it is much to be desired that someone should undertake this.

So far as my information goes, the best of the lochs lie in flat arable or grazing country, and the raising of their level by impounding would flood much valuable territory.

Mr. Dick makes an estimate of powers from a number of rivers, including the Erin, Corrib, Shannon, Bann, Lee, Inny, etc. From what he calls "minimum" flow he estimates that "constant" power is available; from "normal" flow "ten months'" power, and from "augmented" flow (which includes floods), "seven months'" power.

The amount of power as given by him is as under:—

"Constant" power	5,916 h.p.	
10 months' ,,	11,832 ,,	
7 ,, ,,	23,664 ,,	

The total is not very imposing, especially as other writers claim for the Erin alone from 30,000 to 300,000 h.p.

Mr. Dick says that the normal flow—*i.e.* giving ten months' power, may, for areas of 30 square miles and upwards, be taken as 25½ cubic ft. per minute per square mile, being only slightly more than what I estimated for Scotland.

To recapitulate briefly, if we are to pay for this war by acceleration of our industrial activities any scheme for the broadcast distribution of cheap power is of the utmost importance. Water power provides great possibilities in coalless territory and where coal cannot be cheaply imported.

Cheap power means the more universal application of it, with a consequent release of man-power which for many years will be scarce and expensive. Canada at the present time uses about one and a half times the amount of mechanical energy per worker that we do. Schemes for national reconstruction and social betterment are meantime rife, and much is expected of a sound practicable land policy.

I have elsewhere contended that any successful policy for an agricultural renaissance must

be associated with an industrial policy, and utilisation of water power and afforestation are pre-eminently attractive from this point of view.

The rural homes throughout the country are occupied by old people, maintained by their sons and daughters employed in the great cities, and unless the younger generation be found remunerative and attractive employment where they are born they will not settle down there. Moreover, the poverty of our rural districts has been for long attracting attention, and unless something be done which will increase the rateable value there, it looks as if taxation for public services, such as education, poor, roads, sanitation, etc., will eventually have to be met by the State.

Already in some districts in the north of Scotland taxation is in excess of the gross rateable value, and such a condition of things is economically destructive in any State.

It is much to be desired that such work as that done by the British Rainfall Organisation and the Scottish Meteorological Society should receive more support and recognition than it does.

Notwithstanding present-day developments in scientific research, there are still those who believe that the recording of rainfall, temperature, hours of sunshine, and direction of wind currents, is little more than a "harmless craze."

It is quite possible, however, that the development of aerial flight, which will be of immense interest in the future, will direct attention to this branch of science, and that the work of past and present meteorologists will yet be appreciated as it deserves to be.

The paper was illustrated by a number of interesting lantern-slides.

APPENDIX.

SCOTLAND.

Lochs, Drainage Areas, Fall available and Power possibilities, assuming that 24 hours' yield from Catchment Area is utilised in 12 hours; based on ⅔ of a 42-inch rainfall. Efficiency, 75 per cent.

Name of Loch.	Height above sea.	Drainage Area.	Area of Loch.	Fall utilised.	Horse-power.	Point of Development.
	feet.	sq. miles.	sq. miles.	feet.		
Wick—

				(Say	375,000)	

The Clyde, Forth, and Tweed Basins have not been dealt with owing to the important water-supply and other interests already involved, nor have the power possibilities of rivers and small streams been included.

By diversion and linking-up of adjoining catchment areas, and impounding beyond the extent provided for in the foregoing estimate, it may be assumed that for, say, 100 days' supply, 650,000 horse-power is available.

Approximate formula for calculating horse-power as above is $\frac{AH}{3}$, where A = catchment area in square miles and H = fall utilised in feet.

A. NEWLANDS, M.Inst.C.E.

January, 1918.

DISCUSSION.

Mr. C. S. Meik, M.Inst.C.E., in opening the discussion, said the paper was exceedingly valuable, and he hoped it would serve to encourage the development of water power in Scotland. He did not think the author had been quite right in giving an average rainfall of 42 inches for the whole of Scotland. In the eastern part of the Highlands 42 inches of rainfall was high, and one could not rely upon obtaining it, but that figure was very low indeed for the western shores of Scotland. There were districts, for instance, west of the Caledonian Canal, where the average rainfall was over 100 inches, and at Kinlochleven, farther south, it was 86 inches. It therefore followed that the water power available on the western coast would be very much more than in the interior. The author apparently favoured the development of small powers, but personally he did not see how small powers could be developed to advantage, especially inland, unless the power was going to be transmitted to a town, and that involved larger stations so that the power could be generated at one station and transmitted in one line. On the western shores of Scotland he thought there was every possibility of large developments in the future, because the use of power to any extent involved the conveyance of raw materials, and those materials could be conveyed much more cheaply by sea than by railway or any other means. It must not be forgotten, however, that where coal could be obtained at as low a price as 4*s*. or 5*s*. per ton for the production of power—as was the case in certain districts in pre-war times—there was not much margin in favour of water, and the additional advantage of the large population present in a coal-mining district was always an attraction to manufacturers to establish their works there.

Mr. W. Murray Morrison, M.Inst.C.E., heartily endorsed the author's suggestion that the authorities should collect information with regard to rainfall records, water power, and similar matters. In certain Continental countries, such as Norway and Sweden, full information on such subjects could be purchased. He did not agree with the remark made by Mr. Meik with regard to small powers, but thought there were a number of industries which might very well be set up to utilise smaller powers, by which he meant 3,000, 4,000, and 5,000 h.p. On the other hand, there were, of course, certain industries which could not be carried on without a very large amount of power, as, for instance, the manufacture of aluminium. With regard to the employment of labour, as a Highlander it was his proud boast that he had been associated with the establishment of two water power installations in the Highlands of Scotland, where the people employed were chiefly crofters. He believed that the establishment of such installations in the

Highlands of Scotland was the key to the situation which politicians had been striving to find for many years past, because it would lead to an increase in agriculture, fishing, and other industries, including afforestation, which would need serious attention after the war. He did not agree with the author's plea for the nationalisation of the water powers in this country. If the Government were to establish industries in the north of Scotland and work them themselves, progress would certainly be hindered; whereas if private manufacturers were encouraged to extend the use of water power, progress would be found to be very much more rapid. If good and up-to-date houses were provided for the workpeople in those parts of the Highlands where water power was capable of development, labour would be attracted to those places, and the workpeople would be much more comfortable and happy than they would be in the more densely populated districts.

Sir John Benton, K.C.I.E., M.Inst.C.E., thought the Government should make a thorough hydrographic survey of all the waterways in Scotland, because at the present time neither the Government nor the users of power knew much about the matter. Owing to the lack of coal north of the Forth, the Highlands of Scotland were dependent to a great extent upon water power; they had an abundant rainfall which would yield a large amount of horse-power, which should be used to develop industries in those districts. Canada, the United States, and many other countries, had had surveys made of their water powers, but this country had, up to the present, done nothing in that direction. Objection might be taken to nationalisation, but a proper survey of the water powers of this country must be regarded as a national question.

Major-General Sir George Scott Moncrieff, K.C.B., C.I.E., had listened to the paper with the deepest interest, and thought that, although the development of water powers might be left largely to private enterprise, there should be some coordinating influence exercised by the Government to see that the utilisation of those water powers was undertaken on some regular and definite plan. The remarks Sir John Benton had just made about the desirability of a careful statistical examination of the country's resources in regard to water power being made seemed to be a step towards that plan. Any application of those resources should be subject to some central control. The very interesting series of lantern-slides indicated the enormous amount of water power that was being wasted at the present time, and he trusted the matter would not be allowed to drop either by the Government or by the great industrial concerns in the country.

The Chairman (Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.) then proposed a vote of thanks to the author for his interesting paper. In doing so, he said that the Census of Production taken in 1907 showed that in Great Britain at that time 10½ million h.p. was being used in stationary engines of various kinds for the industries of the country, which amounted to a little over 1 h.p. per worker. In the United States of America, in a Census of Production taken two years later, in 1909, the total horse-power used in a similar way was over 23 million, showing that the Americans had developed the use of power to a very large extent. He was interested to learn that in Canada the total consumption of power was greater per head of the workpeople than it was in Great Britain, and he supposed that must have come about since the recent development of water power in Canada. The Conjoint Board of Scientific Societies had been taking an interest in the water power of the British Empire, and a committee had been formed, of which Mr. Newlands was a member, to study the whole question. The committee was trying to obtain information as to the water power of Canada, New Zealand, Australia, India, and South Africa, and had already made some progress in obtaining data from those countries. There was no doubt that within the British Empire there was a very large amount of water power. The largest water power in existence, however, was that of the United States, which had a possible 30,000,000 h.p. That meant that if the United States wanted to displace the use of fuel altogether, or if, after five hundred or six hundred years, fuel became very scarce, they could carry on their industries by the use of water power. The author had estimated the water power of Canada as 17,000,000 h.p., whereas the estimate he (the Chairman) had given at a meeting of the Royal Society's committee to which he referred, was about 11,000,000 h.p., but he thought the author's estimate was very likely the more correct one. The water power available in New Zealand appeared to be about 7,000,000 or 8,000,000 h.p., and even Australia had a greater water power than this country. It did not seem possible, judging by the author's figures, that in England steam power and other engine power could be replaced by water power to any very great extent, but it was necessary in the interests of the future of Great Britain that coal should be economised as much as possible, and that every available means, including the use of water power, should be adopted in order to lengthen the industrial life of Great Britain. If that was not done, our industrial life might come to an end in perhaps about four hundred years. The transition of this country from an agricultural to a manufacturing State, which might be called the industrial revolution, began in the middle of the eighteenth century, and if our coal supply came to an end the industrial stage might terminate about five hundred years hence; and, unless we could obtain other means of getting motive power, a very great rearrangement of the British Empire would be brought about, although Great Britain would still, he hoped, be the centre of the Empire. A

hundred years ago, in the last great war, the population of Great Britain and Ireland was only 15,000,000, now it was about 46,000,000; and if this country became once again an agricultural State that population could not be maintained.

MR. ALEXANDER ROSS (Past-President of the Institution of Civil Engineers), in seconding the motion, said the paper contained a great deal of useful information that could be put to a practical use, and he hoped the Government would see that the water power of the country was utilised in a proper manner for the good of the whole nation

The resolution having been carried, MR. NEWLANDS said he agreed with the remarks that had been made as to the desirability of having a hydrostatic survey of the water power of the country. Mr. Morrison was mistaken in thinking that he advocated nationalisation of water power or anything else; he simply wanted it under proper control. Without some Government assistance the development of water power could not make much progress.

OBITUARY.

RUTH MORRISH DAY.—Many Fellows of the Society will receive with much regret the news of the death of Miss Ruth Day, who has contributed to the *Journal* the clever articles on "Arts and Crafts" which have appeared for the past twelve years in its columns. The first of these was published on March 16th, 1906, and the last on December 21st of last year. Shortly after that date Miss Day was attacked by influenza, followed by pneumonia, which caused her death on the 14th inst.

She was the only child of the late Lewis Foreman Day, the well-known decorative artist and designer, who, up to the time of his death in 1910, was intimately associated with the Society as a member of its Council, and a frequent lecturer. After his death she herself joined the Society (1910). In her youth Ruth Day was associated with her father in much of his work, and acted as his secretary, assisting him in the revision of several of his well-known books on art-workmanship. After his death, she continued similar work on her own account, writing on subjects of applied art in other newspapers and periodicals as well as in the Society's *Journal*. When the war broke out she was engaged on the preparation of a book on old Initials for Messrs. Batsford, the publishers, but the issue of this work was postponed. She succeeded her father as a member of the Committee of the School of Art Woodcarving, and took an active part in its management, interesting herself in the welfare and progress of many of the younger students.

During the last few years of her life she devoted a great deal of her time to mission work in connection with the Church of England. She was an earnest student of theology, and obtained the Archbishop's diploma in that subject, as well as a certificate as teacher. Perhaps her religious work as a lecturer and teacher was really nearer her heart than the artistic pursuits to which she had been trained, considerable as was her capacity for the latter. However, she had made a distinct reputation as a writer on applied art, and had not her promising career been cut short at so early an age—she was a year or two short of forty—she would doubtless have produced more work of permanent value and importance.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, JANUARY 28...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. C. R. Darling, "High Temperature Processes and Products." (Lecture II.)

Geographical Society, Central Hall, Westminster, S.W., 8.30 p.m. General Smuts, "East Africa."

TUESDAY, JANUARY 29...Royal Institution, Albemarle-street, W., 3 p.m. Professor W. M. Flinders Petrie, "Palestine and Mesopotamia: Discovery, Past and Future." (Lecture III.)

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Mr. F. G. C. Baldwin, "Telephone Exchange Transfers and their Organisation."

WEDNESDAY, JANUARY 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir William George Watson, "The Manufacture of Margarine in Great Britain."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Dr. G. E. Smith, "The Reform of the Treatment of Mental Disorders."

THURSDAY, JANUARY 31...Royal Society, Burlington House, W., 4.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Napier Shaw, "Illusions of the Atmosphere; Revolving Fluid and the Weather Map." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Lecture by Dr. C. Atkin Swan.

FRIDAY, FEBRUARY 1...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor A. S. Eddington, "Gravitation and the Principle of Relativity."

University of London, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture III.)

SATURDAY, FEBRUARY 2... Royal Institution, Albemarle-street, W., 3 p.m. Mr. M. P. H. Loyson, "The Ethics of the War." (Lecture I.)

Correction. — The name of Mr. Charles H. Challen, who took part in the discussion on Dr. Clay's paper on "The British Pianoforte Industry" (*Journal* of January 18th, p. 163, column 1), was incorrectly given as Mr. John D. Challen.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes in the City of Westminster.—January 25, 1918.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,402. VOL. LXVI.

FRIDAY, FEBRUARY 1, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 4th, at 4.30 p.m. (Cantor Lecture.) CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." (Lecture III.)

TUESDAY, FEBRUARY 5th, at 4.30 p.m. (Colonial Section.) C. DU PLESSIS CHIAPPINI, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa." The RIGHT HON. VISCOUNT GLADSTONE, G.C.B., G.C.M.G., G.B.E., will preside.

WEDNESDAY, FEBRUARY 6th, at 4.30 p.m. (Ordinary Meeting.) WILLIAM FRECHEVILLE, A.R.S.M., F.G.S., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of the Mineral Resources of the British Empire." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., Member of the Council of the Society, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

JOURNAL.

Owing to the enormously increased cost of printing and paper, it has been found absolutely necessary to discontinue the issue of double numbers of the *Journal*. Reports of the Ordinary Meetings and meetings of the Indian and Colonial Sections will be given, one each week, in chronological order. It is much regretted that a break should be made in the custom of publishing the reports of the Wednesday meetings on the following Fridays, which has been maintained since the foundation of the *Journal* in 1852.

This change is only a temporary war measure, due entirely to the necessity for retrenchment in every possible direction, and it is intended to revert to the former practice of prompt publication as soon as circumstances permit.

The report of the Eighth Ordinary Meeting, on January 30th, when a paper on "The Manufacture of Margarine in Great Britain" was read by Sir William George Watson, Bt., will be published in the next issue of the *Journal*.

CANTOR LECTURE.

On Monday afternoon, January 28th, Mr. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, delivered the second lecture of his course on "High Temperature Processes and Products."

The lectures will be published in the *Journal* during the summer recess.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, January 17th, 1918; The RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., in the chair.

THE SECRETARY of the Section announced that Lord Sydenham, who had promised to preside, could not attend, as a Bill to which he had amendments was coming on at the same hour in the House of Lords. The following letter had been received from him:—

101, Onslow Square, S.W.,
January 16th, 1918.

DEAR SIR,—I deeply regret that I am unable to take the chair to-morrow. From the first, I have taken a warm interest in the great undertakings of the Tata Company. They have shown that steel of the highest class can be made in India on a great scale, and the work that is now being carried on and developed is of the utmost value to India and to the Empire. During the war, the advantages arising from the output of steel have been most important. India will become self-supporting in this respect, and on the basis of Indian steel a large number of other industries will be rapidly

built up. It is not too much to say that Messrs. Tata have given a new impulse to Indian industries, which will have incalculable results in the near future. The hydro-electric installation in the Bombay Presidency is the finest of its kind in the world, and it has proved what Indian capital can accomplish under wise and sound direction. What India needs most at the present time is industrial leaders like the Tata family, who, by their enterprise and the confidence they inspire, can turn to account the immense resources of the country and spread prosperity far and wide among the people.

I am, yours faithfully,

SYDENHAM.

The paper read was—

THE TATA IRON AND STEEL WORKS: THEIR ORIGIN AND DEVELOPMENT.

By H. M. SURTEES TUCKWELL, M.I.Mech.E.

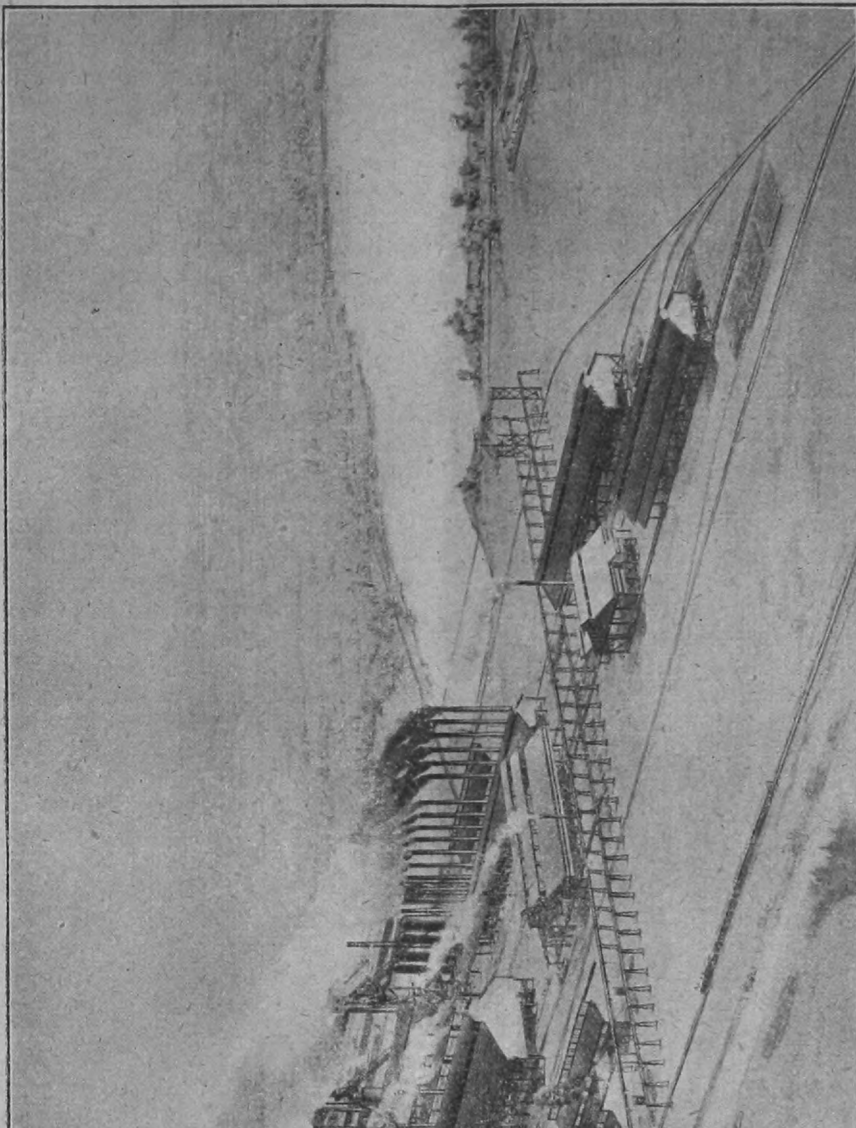
I should first express my very high appreciation of the honour your Council has done me in inviting me to read a paper before you, and, by recording my sense of unworthiness, to secure a measure of your sympathy and indulgence in the shortcomings of my effort to interest you this afternoon—shortcomings of which no one is more conscious than myself.

The main lines which I desire to traverse in this paper are the Tata Iron and Steel Company, its origin and development, and the effect which it will have upon the industrial prosperity of India.

It is supposed that ancient India acquired the art of smelting and forging iron from the Chinese. It is, at any rate, certain that in the early ages Indian artificers possessed, to a high degree, skill in smelting and fabrication of metals. This is witnessed in the wonderful workmanship of ancient weapons still found in India, and the 3,000-year-old iron pillar of the Kutab-minar near Delhi, the methods employed in the construction of which are unsolved by metallurgists of to-day. In the Middle Ages the craftsman's dexterity was still maintained, and India supplied the materials from which the famous Damascus steel blades were made. The industry flourished till the downfall of Sikh independence in the last century, chiefly for the manufacture of swords and armour. Progress was extremely slow, and to this day the most primitive methods of smelting are found among the jungle dwellers.

The first attempts to establish an iron and steel industry on Western lines in India were made by Mr. Joseph Marshall Heath, a retired Madras civilian and a friend of Charles Dickens, who obtained a grant from the directors of the East India Company and established works at Porto Novo, on the Madras coast, in 1830. The expenses of buildings and experiments exhausted his funds, and the Government gave him a loan of 5¾ lacs of rupees, of which his debts absorbed 4¾ lacs. He had installed furnaces capable of producing forty tons of pig-iron weekly, and his intention was to manufacture bar iron and export to England in competition with Swedish iron. He was faced by numerous difficulties. His boiler burst, and the blowing engines had to be driven by bullocks. His operators lacked practical experience; his limited capital hampered him; the quality of the ore varied; and the supply of charcoal used for the reduction of the ore was insufficient. It may here be noted that up to that time all iron smelters in India utilised charcoal as fuel. It is recorded that in Mr. Heath's furnace 3¾ tons of charcoal were required per ton of iron. In the latest American practice, which, we believe, can be realised in India, one ton of pig is produced with one ton of charcoal. His costs amounted to Rs. 45 for smelting one ton of ore. In 1837 he sought a fresh loan from the Government, who refused. Poor Mr. Heath, penniless and broken in health, died, and in 1853 a new company, the East India Iron Company, took over the undertaking, which, however, stopped altogether in 1874.

The second attempt was in 1875, when the Barakar Iron Works Company started on the Jherria coalfields, 143 miles north-west of Calcutta. They likewise failed, and closed in the same year. The Government restarted operations in 1881, and in 1889 made over the concern to the Bengal Iron and Steel Company, who have successfully produced pig-iron ever since. In 1905 the Bengal Iron and Steel Company opened a steel department, but it was found there was not sufficient demand for small steel sections at that time to give continuous rollings of any one section to work economically. As an instance of this, the Government orders for six-months, a total of 180, amounted to less than 1,000 tons and included seventy different sections. Manufacturing under such conditions resulted in a considerable loss of money, and the steel department was closed down in twelve months after starting. The Company, however, has a large output of pot sleepers, cast-iron pipes, and mill columns, and specialises in foundry pig-iron. There is little doubt that the representations made by the Bengal Iron and Steel Company to the Government, although they did not produce the practical support which was hoped for at the time, nevertheless paved



TATA IRON AND STEEL COMPANY, LIMITED, KALIMATI WORKS, BENGAL, INDIA.

the way for the Tata Iron and Steel Company, who have obtained a large measure of support and practical assistance from the Indian Government.

The third attempt was that of the Tata Iron and Steel Company, which was formed in 1907.

It would be remiss in dealing with the origin of this Company to pass on without a brief sketch of the life of the founder, Mr. Jamsetji Nusservanji Tata, who was born at Navsari, in Baroda State, in 1839. His parents belonged to the priestly caste of the Parsee community, and his biographer records that the small town of Navsari was a stronghold of the Zoroastrian priesthood, whose two principal characteristics were doggedness and perseverance. Such an atmosphere contributed in no small measure to the formation of Mr. Tata's character, and the acquirement of these attributes enabled him to realise his ambitions in the face of obstacles, insurmountable to a man of less determination.

At thirteen years he was sent to the Elphinstone College at Bombay, where he studied for six years. His commercial training was obtained in his father's Bombay office, and in a Hong-Kong office. Subsequently, after visiting Manchester, and there studying textile manufacture, he established a cotton-mill at Nagpur. A good many initial difficulties had to be surmounted, but Mr. Tata was eventually rewarded by unprecedented success, and the Company had, up to the end of 1913, made a present to their shareholders of $2\frac{1}{8}$ shares per share held. New mills and other enterprises followed, and after 1895 he resolved to realise the three great ambitions of his life, which he had been revolving in his mind for twenty years. These were: (1) the smelting and conversion into steel of the iron ore known to exist in large quantities in India; (2) storage and utilisation for industrial purposes of the immense monsoon waters which fall annually on the summit of the Western Ghats; (3) institution of a scientific research laboratory, whose investigations should foster and develop the innumerable Indian resources hitherto imperfectly explored.

Mr. Tata had first obtained a concession to work the Lokara ore with Warora coal; this coal proved unsuitable for coking, and he relinquished the scheme. In 1899 Lord Curzon introduced new rules for mining and prospecting, which materially facilitated industrial development, and at the end of the last century Mr. Tata visited England, saw the Secretary of State for India (Lord George Hamilton), who gave him considerable encouragement and promised Government help. On his return to India Mr. Tata obtained permission to work the Chanda iron ore deposits. In 1902 he visited America, obtained expert advice, and, amongst others, saw Mr. Julian Kennedy, and engaged Mr. C. P. Perin, a noted New York mining engineer, whose associate, Mr. C. M. Weld, left for India shortly afterwards.

At this time Mr. Tata associated with himself in the concession his son, Sir Dorabji Tata. Prospecting was now actively in operation. Mr. Tata's speculation amounted to £35,000, which was sunk in preliminary expenses before the Company was floated, a good deal of this sum representing the cost of flotation. The preliminary investigations were necessarily protracted, as when ore deposits were located much expert analysis was needed to determine the economic possibilities of smelting the ore, and, this point having been established, ascertain the availability of suitable coal within reasonable distance. Many properties were investigated and relinquished. Eventually Mr. Weld located a deposit of one of the richest iron ores in the world, the Rajara Hills, Central Provinces, which are practically solid iron, and the Dhullee Hill near by, which also provides a very rich ore. A prospecting licence was secured, and diamond drilling revealed an ore yielding about 66 per cent. pure iron. Finally, through Mr. Perin's and Mr. Weld's investigations, the deposits at Gurumaishini in Mourbhanj were found to offer the most favourable conditions for immediate operation, these being materially influenced by the proximity of the Jherria coalfields. Prospecting and mining leases were obtained from the Maharaja of Mourbhanj, conditionally upon the total area taken up not exceeding twenty miles. Prospecting continued till 1909, when a thirty years' mining lease with option for renewal for a smilar period was obtained by the Tata Iron and Steel Company. Government sanction was secured in 1910, and the Tata firm now had concessions for Gurumaishini and other iron ores in Mourbhanj, Dhullee, Rajara and Chanda iron ore in Central Provinces, acquiring also their own manganese mines at Ramramah, Central Provinces. Samples of coal from different seams in the Jherria coalfields were sent to America and Europe for analysis and coking test, and it was found that while they contained a high percentage of ash, they yielded sufficiently hard coke for blast furnace purposes, nor was the high ash an objectionable feature when reducing a rich ore like the Gurumaishini ore, as it helped to form a slag. Limestone of

excellent quality at Jukehi near Katni, and dolomite at Panposh, were secured.

The result of expert investigations in Europe and America were carefully studied with a view to determining how far Western practice might be adopted in India. The information thus obtained was devoted to the establishment of a research laboratory at Bangalore, endowed by Mr. Tata with 30 lacs, or £200,000. The site was given by the Maharaja of Mysore, and further financial assistance by the Government of India. The equipment was to include: (1) Scientific and technical; (2) medical; and (3) philosophical and educational laboratories, together with libraries, museum and other essential factors, and in 1911 actual work commenced. Fate decreed that the originator of the scheme should not live to realise the ambitions of his life. Dryden has said, "Pioneers from Moses onward, see yet cannot achieve their aims, but they make God's kingdom possible," and often, as in this case, their successors carry on their work. Mr. Tata's two sons and his cousin and partner, Mr. R. D. Tata, assumed the mission which had survived its founder, and their determined energy and whole-hearted co-operation have been rewarded by the consummation of Mr. Tata's three ideals. To-day the research laboratory, after a chequered period of constructional and preliminary difficulties, is now in full operation, and, according to Mr. Chatterton, Director of Industry in Mysore, the work of that institute in 1915–16 has in its industrial results more than repaid to India the whole of the outlay expended upon it. The monsoon's rains are compelled to drive fourteen cotton-mills of Bombay, and the Tata Iron and Steel Company during 1916 produced 187,000 tons of pig-iron and 125,000 tons of steel.

The Tata Iron and Steel Company, Ltd.

When, some years before the steel company was established, their consulting engineer met in conference a number of railway magnates and experts, he was told that steel rails could never be made in India from indigenous materials. As an instance of their failure properly to assess the situation, I may remark that a large tonnage of rails has for a year and a half been shipped regularly to Mesopotamia, and other theatres of war, and played no mean part in the relief of Baghdad.

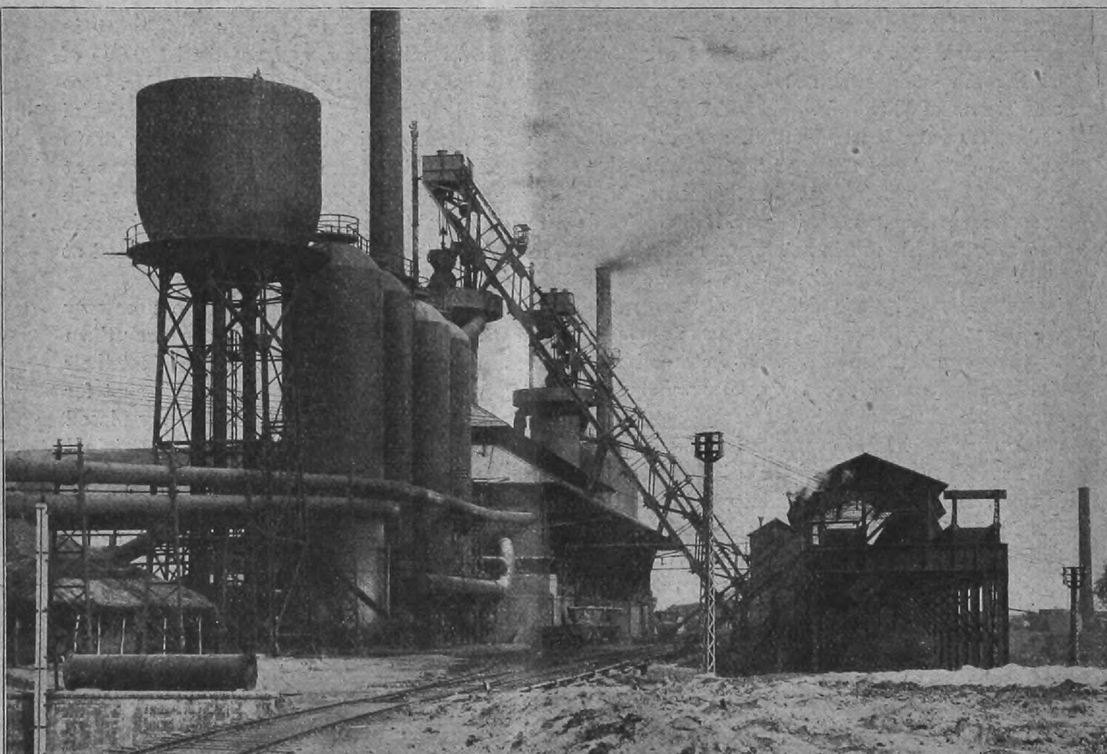
Prior to the geological survey of India, very little was known of the metalliferous resources of that country. Valuable assistance was rendered by Lord George Hamilton, Lord Curzon, Sir John Hewett (Member of Council), Mr. Harvey (Secretary of Government), and Sir Thomas Holland. To the latter gentleman, as an expert, the entire Tata scheme was referred, and he appears to have made a wholehearted commendation of the American experts' report to the Tatas.

In 1907 the Tata Iron and Steel Company was formed, with a capital of Rs. 2,31,75,000 (£1,545,000). The Dhullee-Rajara ore deposits had been discovered by Mr. Bose, an Imperial geologist, and, as before mentioned, Mr. Tata's private survey had proved them. The same gentleman, after resigning the Imperial service, became the private geologist of the Maharaja of Mourbhanj, who took a great interest in Mr. Tata's enterprises, and acquired £20,000 of shares in the company when formed. Mr. Bose had lately discovered iron ores at Gurumaishini in the Mourbhanj State, and the Maharaja invited the Tata firm to smelt these ores at Gurumaishini. Geographical conditions made this undesirable, but the firm were glad to acquire mining rights for the ores which are smelted at Sakchi.

The initial stages of locating the necessary raw materials and securing rights to work them were now completed, and the explorers set their attention to the selection of a suitable spot for their assembly, which might be centrally placed in regard to the various supplies. Original intentions favoured Sini, a junction on the Bengal-Nagpur Railway, in the Singbhum district, but the construction of an essential in the shape of a reservoir, estimated at from Rs. 15–18 lacs, made further search desirable, and eventually a site near Kalimati Station, eighty miles east of Sini Junction, was selected early in 1908. Here, on a territory more or less covered with jungle, populated by a few scattered Santali people, probably the most interesting undertaking in the history of industrial India was initiated. A small Indian village known as Sakchi has given its name to the works and township, which in magnitude may ere long rival many a Western steelworks.

When the Steel Company was formed, twenty square miles were obtained on lease for a number of years, and of this property about five square miles were originally acquired through the Land Acquisition Act in perpetual ownership. Since that time further acquisitions have been considered and are now in process of being made. The Government had given necessary mining concessions, and the Bengal-Nagpur Railway promised reduced freights for construction

material and plant, and the assembly of raw materials. The Indian Railway Board, as a mark of sympathy and goodwill, had placed an order for ten years' annual supply of 20,000 tons of steel rails, the conditions being that the rails must comply with Government specification, and the price be no more than similar goods delivered c.i.f. Indian ports. They further constructed forty miles of line connecting Kalimati with the Gurumaishini ore mines, and made special valuable concession freight rates dependent on certain ton mileages covered per year. The local Government also greatly south the estate is bounded by the Bengal-Nagpur Railway, whence raw and finished materials are transported. On the east is a range of rocky hills, from 500 ft. to 3,500 ft. in height, on the summit of which it is proposed to create a sanatorium and hill station. Here the vigorous may obtain a week-end of rest and enjoy somewhat cooler conditions, and the sick or convalescent recover without the fatigue and expense of a journey to Simla or other established stations. The health conditions at Sakchi are excellent. The station is 532 ft. above sea-level, with a natural drainage on each side.



BLAST FURNAECS.

assisted the Company in securing land grants and avoiding administrative delay.

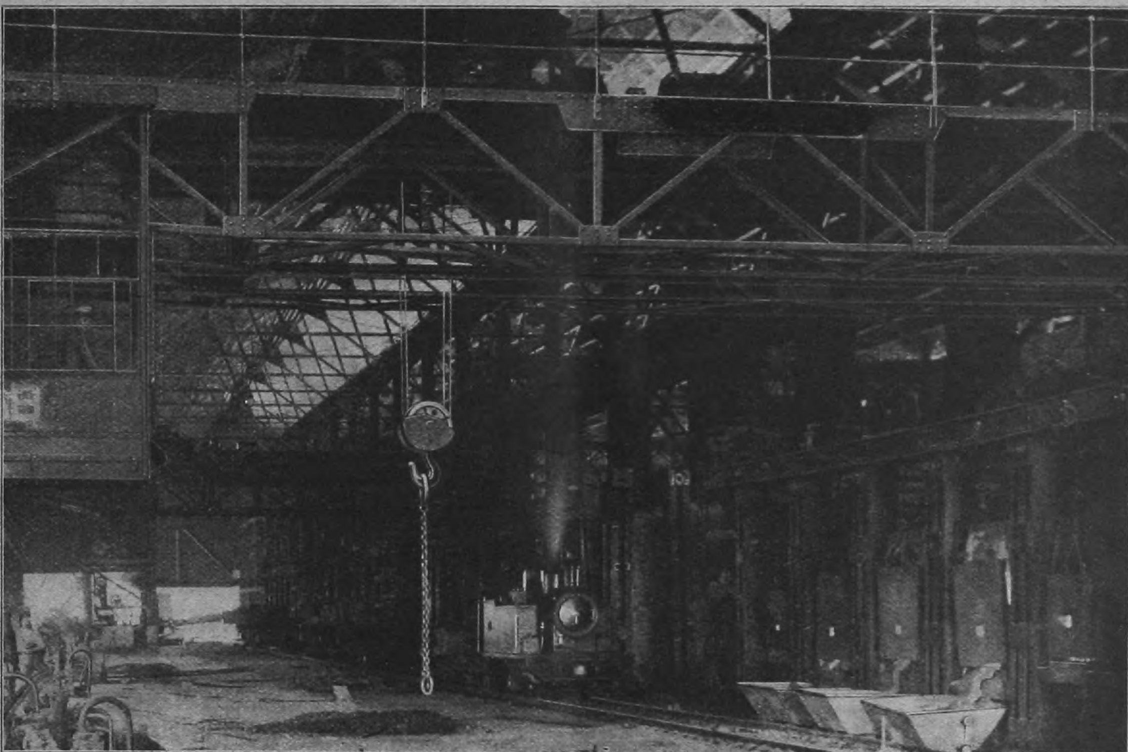
The works lie 150 miles west of Calcutta, 40 miles from the Gurumaishini iron ore mines, and 115 miles from the Jherria coalfields, and the careful judgment of the firm's consultants provided that the works should be bounded on the north by the Subnareka River, and the west by the Khorkai River. The former had never been known to run dry in the hottest summers, and thus afforded ample water-supply, a most necessary feature in a steelworks. On the The climate is healthy and dry, and though the temperature reaches 118° F. in the shade during hot weather, it is not unbearable. Surface drainage is very satisfactory all over the property. At a depth of from 4 ft. to 5 ft. is found a stratum of mica schist, forming an efficient foundation for heavy machinery. At the time of which we speak land was not costly to acquire, and had little agricultural value.

The plant as originally erected consisted of two blast furnaces, designed for 175 tons per day, or 120,000 tons per annum; four Siemens-

Martin open-hearth furnaces, with an output of 85,000 tons ingots per annum; blooming mill; rail and beam mill; two bar mills; 180 Coppee non-recovery coke ovens—the total output of finished steel being 72,000 tons per annum. A study of statistical reports shows that before the Tata Iron and Steel Company began operations, India's contribution to the total world production of iron and steel was practically negligible, and in 1906 amounted to only one two-thousandth part of the annual world production of pig-iron, while for steel she had to entirely depend on foreign countries.

labour; ample supplies of rich ore and raw materials, were the most obvious of these; but, on the other hand, we must not forget the previous disastrous attempts to make steel; the unknown effects of climatic conditions; the untrained and physically inefficient native labour; the excessive cost of imported labour; and the experts' expressed opinion that steel rails could never be made in India.

In February, 1908, camps were formed near the old village of Sakchi, and the work of jungle-clearing began in a district where wild beasts had hitherto roamed at will. Hundreds of



STEELWORKS.

The Indian railways demanded an ever-increasing supply, and collieries, cotton and jute mills, were becoming an important market for western exporters. Here, then, was an opportunity possessing many of the elements essential to success, and only awaiting the courage and determination of a pioneer.

In India, Burma, and the Far East, the manufacturer had unquestionable advantages over foreign competitors. Elimination of freight charges; cost of mining and transportation the lowest in the world; an abundance of cheap

bullock and buffalo carts arrived and transported rails, sleepers, bricks, cement, and other construction materials from Kalimati, and assembled them in huge piles on the works' site. Arrangements were made for a water-supply from the Subnareka River, buildings sprang up, and, by the end of the year 1908, several of these were completed. A most important adjunct was the construction of a macadamised road from Kalimati station to the works and a broad-gauge railway, three miles long. By August, 1909, this was open for traffic, and

proved invaluable for transport of heavy machinery and stores. The diminutive station at Kalimati was now rebuilt, and a large goods yard added.

In 1910 the waterworks were completed, a pick-up weir was thrown across the river, a pumping station with a capacity of one million gallons per twenty-four hours erected on the river bank, and a 28-in. pipe-line laid up to the works, a distance of 9,000 ft. Some five acres of suitable ground were selected, a dam constructed to form a bund or reservoir, in which the water might be stored for works and domestic use. The town included bungalows fitted with electric light, fans, and water service; cottages, coolie lines, institute, court house, police-station, and hospital. A soda-water factory and ice plant were provided, as the drinking of unsterilised water is attended by considerable risk.

Machinery began to arrive in 1910, and the coke ovens (foundations for which were begun in the latter part of 1909), were fired for the first time on October 12th, 1911. On November 2nd, 1911, the first or "A" blast furnace was blown in, and "B" furnace on September 25th, 1912 Early in the same year the steelworks began operation, and the first piece of ingot steel was rolled on the blooming mill on February 16th, 1912, while a month later the first rails were produced, being followed in October by the bar mills producing flats, squares, and rounds. Up to this time 31,000,000 cubic feet of brick, masonry, and concrete, 7,000,000 firebricks, and 24,000 tons of structural steel, machinery, boilers, etc., had been worked into place. To effect this, 5,426 waggons had been brought over the lines to Kalimati in 1911, and 15,800 waggons in 1912. Happily anxiety in regard to the supply of labour was not realised, and about 4,000 Indians were employed during the construction period. Many difficulties were experienced and surmounted, as one department after another was started up. This being the first time that the manufacture of steel under modern conditions had been undertaken in India, absence of previous experience of working under tropical conditions, and employment of entirely unaccustomed labour were excuse for failure to attain results achievable under Western conditions.

In the initial stage there was much alteration, pulling down, and reconstruction. Steel output fell far short of standard, and transient labour imported from Germany handicapped the efforts of the management. Perseverance and courage on the part of the firm, the staff, and their expert advisers, eventually triumphed, and the preliminary period was educational for the workers and enabled the management gradually to reduce the percentage of European or American employees and substitute Indian labour. To-day in the bar mill three eight-hour shifts, which would require the employment of twenty-seven Europeans, are manned by a crew of twenty-five Indians who run the plant economically with only two European superintendents, and in other departments similar reductions have been made. The chemical laboratory originally employed five European chemists. Now the chief and assistant are Europeans, the remainder of the staff of twenty-one being Indians. In addition to the works laboratory there is a Government laboratory, under the charge of Dr. M'William, resident Government Inspector, and formerly of Sheffield University; also a physical laboratory equipped with 100-ton Buckton testing machine, and other test apparatus.

In very many instances Indian workmen have shown themselves possessed of extraordinary skill and manual dexterity, and the electrical department is under the superintendence of an Indian gentleman, a graduate of an English university, assisted by a staff of Indian wiremen and electricians.

The coke ovens and blast furnace department gave satisfactory results from the first, and to some extent compensated for the anxiety and losses due to the disappointing results from the steelworks. Then when most of the difficulties had been overcome, the war broke out, and added a new source of apprehension to the management. The open hearth department was being operated by a German crew, and it was necessary to make immediate arrangements for the substitution of an English crew, the Germans being interned at Ahmednagar.

Mr. Perin, to whom reference has already been made, had now taken charge in an advisory capacity. Efforts were maintained to reduce costs of production, and essential additions were made. The 180 Coppee coke ovens proving insufficient, fifty Koppers by-product ovens were ordered in 1914, and began to turn out coke in 1916, the by-product plant being started up shortly after, together with the manufacture of sulphuric acid, for which an equipment with a capacity of 40 tons weekly was erected. Sulphate of ammonia and tar were now added to the sales list of the Steel Company, and materially reduced the manu-

facturing cost of coke, and consequently pig-iron.

The blast furnaces designed for 175 tons per day each, are turning out 280 tons as a result of Mr. Perin's alterations, and the receipt of new and more powerful blowing engines is expected to reduce coke consumption to well below one ton per ton of pig-iron.

A very interesting experiment is shortly to be tried in Mysore. The Government of that State have decided to erect a charcoal blast furnace, and have appointed Mr. Perin as their consulting engineer. He has placed orders for the equipment in America, and the undertaking is to be managed by the Tata Iron and Steel Company. It is proposed to fell and transport timber from the vast forests of Kadur and Shimoga, and convert it into charcoal at Benkipur. Iron ore will be mined at a distance of twenty-five miles, and a high-grade charcoal iron produced. It is also intended that acetate of lime, alcohol and other by-products will be extracted, and calcium carbide may be manufactured, using the breeze or such portions of the charcoal as cannot be used in the blast furnace. The plant will be constructed and run by the Tata Iron and Steel Company.

In 1916 a world shortage of ferro-manganese was experienced, and great difficulty was found in providing the Sakchi furnaces from this country. One blast furnace was accordingly put on to this manufacture, and 3,000 tons were made, of slightly lower manganese content than is used here, but quite valuable for our works purposes, and over 1,000 tons were sold to America. A special foundry had been built for making cast-iron pot sleepers. Blast-furnace slag, which was used for filling purposes or was piled up in unsightly heaps, was being made into granulated slag bricks, more durable than common red brick; also, by adding phosphoric rock to the slag, a valuable fertiliser will be produced.

Silica and magnesite bricks originally imported from Europe were being made locally from indigenous materials, and latest results show that the Company will very soon be altogether independent of outside sources of these supplies, a very important matter, as the consumption for the next three or four years will be at the rate of 40,000 bricks per day. The Company now make their own ingot moulds, rolls both steel and iron, standard templates for rails, and participate in bricks made locally from their own magnesite.

Visitors to the steelworks coming from Bombay usually arrive in the darkness of the small hours. The flames of the blast furnaces and coke ovens are visible for several miles, a striking contrast to the silent blackness of the jungle being traversed. A tour round Sakchi by daylight makes a very favourable impression —wide roads, admirably disposed and planted with trees, airy bungalows each with its garden, many of these radiant with flowers often grown from English seeds. In the centre of the European town is a wide maidan, or common, where games are played, cricket and football being very popular. Indians have quickly adapted themselves to football, which they play with bare feet. The Babus, who generally wear slippers, kick them off when playing, and apparently suffer little inconvenience from the nature of the ground, which is very hard and covered with small stones.

A fine institute faces the maidan, and contains concert hall, billiard rooms, reading rooms, for men and women, while in the adjacent grounds are tennis courts and bowling alley. A company of the Chota-Nagpur Light Horse has been formed, and the firm provided a rifle range and armoury.

Two motor-buses take passengers to and from the works and Kalimati Junction, thus freeing the branch line of passenger traffic.

A church was completed about a year ago, and is entirely constructed of slag bricks. These are composed of a mixture of blast-furnace slag and lime, and merely dried in the sun. They are pleasing in appearance, and said to be more lasting than common brick. Church of England and sectarian services are held. The Bishop of Nagpur pays occasional visits and a missionary spends one Sunday in four. There are many Indian Christians, and attendance at a service specially for Indians, where prayers, hymns and sermon are in Hindustani, is an impressive function.

We have followed the development of the steelworks through its early stages, and reached the period when all departments were operating satisfactorily. During the second year of the war all the steel output of the works was at the disposal of the Government; shell steel was being supplied to Indian munition works, rails to Mesopotamia. The demand for more and more steel had determined the firm considerably to enlarge their manufacturing capacity and the consulting engineer was instructed to draw up a report on a generous scale for extensions. It has been shown that hitherto pig-iron, steel rails up to 100 lb. per yard, joist,

angles, channels, squares and rounds, comprised the total diversity of output. The tonnage of pig-iron and steel corresponded approximately to the Skinningrove or Frodingham Iron and Steel Company of this country.

The report on extensions was submitted in March 1916, and acted upon in the following autumn. War conditions made it very difficult to purchase complete plant, and it was therefore decided to procure machine tools and equip a large machine-tool shop, and manufacture the bulk of the new plant at Sakchi. The consulting engineer secured office accommodation in New York, engaged draftsmen and technical staff, and began the layout of the new works extensions and the design of the various units. These will comprise two blast furnaces of the latest American design, having an output of 600 tons each per day; a well-designed blast furnace has also been bought second-hand, is being pulled down and will very shortly be re-erected at Sakchi, for the manufacture of ferro-manganese. So large a tonnage of pig-iron will require ample coke, and 200 Wilputte coke ovens, each of 13 tons capacity and having a coking time of eighteen hours, are being erected. The annual total coal consumption will be 1¾ million tons. The Company has strengthened its position in the possession of raw materials by the acquisition of new properties in iron ore, coking and gas coals, steam coal, dolomite and limestone. The Company would not be held up by alien ownership of raw materials necessary to its existence and growth, and it may be presumed that the establishment of the Industrial Bank and the projection of a shipyard are due to the realisation that cheap finance and transport are as essential to the life and fulness of industry as raw material.

A greater diversity of products has been arrived at in the extension programme, and there will be made ship and boiler plates; sheets and tinplates; corrugated sheets, for which a very large market exists in India; cast-iron pipes to 24 in. diameter; wire rods and wire; pressed steel sleepers; patent steel piling sections; also a structural shop for bridges, roofs, and buildings; and a waggon factory for railway cars and waggons. In addition to the above articles made by the Steel Company, it is intended to attract a number of subsidiary companies with their manufactories adjacent to the steel-works, and negotiations are in progress with first-class firms, having as an object the manufacture of butt and lapwelded steel tubes; enamel ironware; smelting of zinc; an engineering shop for engines, boilers, and general plant; a shipbuilding yard; an electric repair and construction shop; a manufactory for various chemical industries. A textile plant manufactory may be established if a suitable opportunity offers, and a list of many other industries has been compiled which may be added as the scheme develops. The Steel Company are able to offer many attractions to such subsidiary companies as may be associated with them—cheap land, electric power and light, coal, coke, gas, railway facilities, advice and assistance in the layout and construction of their works, necessary housing accommodation for their employees. Pig-iron and steel will be drawn from the Tata Company in whatever form best suits the user.

To provide ample materials for all the above purposes it has been decided to add the following plant (orders for essential details were placed in America, the resources of this country being entirely devoted to war purposes, while the rolling-mill housings, castings, and bulk of the heavy components are now being made in the workshops at Sakchi):—Blooming mill; Morgan continuous sheet bar and billet mill; Morgan continuous merchant mill; plate mill; wire-rod mill; sheet mill; second rail mill; pig-casting machine; steel sleeper presses; cast-iron pipe foundry; bolt, nut, and rivet works.

The four Siemens-Martin 40-ton open-hearth furnaces have been enlarged to 50-ton, and two new 50-ton open-hearth furnaces added during 1917, enabling an output of 18,000 tons per month to be maintained.

These will be further supplemented by a duplex process of steel manufacture, which very materially reduces the time of conversion. Molten pig-iron will be carried in ladles and stored in a 3,000-ton mixer, from thence 20 tons at a time will be transferred to a Bessemer converter and blown for twenty minutes, during which time the silicon will be eliminated. This blown metal will be conveyed to a tilting furnace, and after some three hours will have been converted into steel conforming to the desired analysis. It is then tapped and cast into ingot moulds of latest improved type, and the moulds removed to an open-air stripping ground, where the heat given off will disperse with least inconvenience to the workers.

Three 6-ton electric furnaces will produc refined steel suitable for springs, tool steel, etc., or may be devoted, should occasion demand, to making ferro alloys.

Ingots will be 24 in. by 24 in. for all except

plate mill, for which special slab ingots are to be cast, thus reducing much of the preliminary blooming and rolling. A large range of soaking pits will receive the ingots and effect a uniform distribution of heat throughout the body of the ingots before they enter the cogging mill. From thence the ingot is transferred to an electric tilting chair, which deposits it on the roller tables, which in their turn pass it to the cogging mill.

To operate all these additions it has been necessary largely to augment the power plant. Twenty 500-h.p. Wickes boilers, arranged to be fired with blast-furnace gas, are in course of delivery, a second large power-house will receive one 5,000 and one 3,000 kw. high-pressure turbo-generators, and a 2,000 h.p. mixed pressure generator, steam for the latter being principally obtained from the exhaust of the three existing rolling mill engines. Drive for the remaining rolling mills will be by electric motors. Power will be generated at a pressure of 10,000 volts, and reduced at two transformer stations, placed in convenient positions in the works.

Some twenty-five cranes have been ordered, ranging from 120-ton ladle cranes to 10-ton shop cranes.

An important addition will be a new works office building at Sakchi, at an estimated cost of £38,000. This will have seven storeys, and be constructed on the American principle, the skeleton of the building being composed of Tata steel sections, on which the floors and walls are carried, and outside the main walls broad verandahs will afford shade to the rooms. Lifts at three of the four corners will provide access to all parts of the structure, and a system of washed and cooled air will ensure ventilation throughout the building, an intake for the air being formed in the fourth corner.

The handling and transportation of the large quantities of raw and finished material demands special study, and our consultant has evolved a system of tracks, which, while to his expert mind falling short of the ideal, due to the difficulty of its inclusion in the original layout, still presents a simple and economical solution to the railway facilities, and in eliminating congestion in shunting operations is conducive to reduction of costs in this important and often neglected department. Five locomotives are on order to supplement the five now operating the traffic of the works, and a number of additional waggons for coal, ore, etc. The necessity for these will be realised when I state that the approximate increase in traffic amounts to 253 million ton miles. The immense difficulties of carrying out all these diverse extensions in war time will be appreciated by those familiar with present conditions in regard to manufacture and export. A number of ships carrying material have been lost, and the replacements occasioned serious delays. It is due to Mr. Perin's genius that we have so far surmounted them, and to his untiring energy that we confidently look for final achievement.

Welfare work will form a substantial feature of the new extension programme, and with this I would now deal. It may be predicated that the standard of Indian unskilled labour is 300 years behind that of Europe, and while in some directions Indian workmen rapidly acquire extraordinary dexterity, they are extremely conservative, their domestic habits, environments, creeds and caste prejudices, forming a serious barrier to the cultivation of Western methods. The question of the elevation and education of the labourers and their families must be approached with great judgment and caution. It is the ambition of the directors to ensure best possible conditions of employment for their workers; healthy dwellings and work-places; skilled medical attention in accident or sickness; supervision of infant and child life; facilities for recreation hitherto unknown to them, to which they take very kindly; adequate pay for their labours; nourishing food at reasonable prices. The last two may be provided through the medium of a co-operative store and co-operative bank, whose activities will encourage thrift and facilitate a scheme for a payment of bonus in addition to weekly wages. This bonus paid into the co-operative bank would enable a credit to be established at the co-operative store for each depositor, who could then secure goods against his credit. It is hoped that the usurious moneylender may be excluded from the station by these means.

Experts like Mr. and Mrs. Sidney Webb, Miss Harrison and Professor Urwick, have been consulted, and it is intended to send a trained welfare worker to Sakchi very shortly, who may assist and advise the management in the organisation of this department.

Among the first institutions at Sakchi was a hospital, fully equipped with modern devices and controlled by an Indian doctor, whose skilful direction during the past eight years leaves nothing to be desired. The number of patients treated during the year ending December 31st, 1916, was 154,857, over 40 per cent. of whom were drawn from a radius of twelve to fifteen miles, representing a population

of 60,000 souls, only half being connected with the Tata works. The population, it is anticipated, will reach 100,000 to 150,000 when the extensions are complete, and a new large hospital and all its essential details will be installed, at a cost of £40,000. A rest house was provided in 1915 for the women working at the coke ovens, in which they might rest and sleep, and a crèche for their children, who are cared for by an Indian nurse.

There are three schools: firstly, the Mrs. Perin Memorial School, corresponding to an English primary and middle school, the average attendance being 162. It is partly maintained by the Tata Iron and Steel Company and partly by the Government grant. Secondly, the Night School, attended by about seventy chokras, or boy messengers, employed in the works. It is free, and two hours' nightly tuition is given in English and mathematics. Thirdly, the Mechanics' School, for the mistri class or mechanics. Elementary mechanics and drawing are taught. This school is partly financed by the company and partly by Government grants.

There is contemplated in addition to these a Girls' School, also a school open to all paying higher fees in which the curriculum sanctioned for European children by the Department of Public Instruction will be adopted. The directors are closely watching the schools, and, if they show success, are prepared to instal a general scheme of education in the three "R's" not slavishly modelled on the departmental curriculum

The juxtaposition of different white races to each other, and to the varied coloured colonies all in the trying tropical climate, no doubt tested the statesmanship of the men at the head of the Sakchi settlement. An adjustment is being gradually worked out—partly by elimination, as of the Germans, partly by the supersession of all foreigners by the people of the land, and partly by understanding promoted by time and habit.

It is projected that a model laundry, bakery and kitchen will be established, and women encouraged to attend and learn economical and hygienic methods. A model dairy and farm are contemplated, where experiments in the use of fertilisers and scientific agriculture may be carried out. Allotments are to be provided for all who care to cultivate them, and means are to be adopted for the encouragement of handicrafts. It is suggested that an annual exhibition might be held, say, on Christmas Day, where prizes would be awarded for the best production in each category. Education will form an important feature of this work, and in its elementary stages may take the form of instruction by pictures and model making—a combination of Kindergarten and Sloyd. Due attention to health and medical inspection of all new employees and subsequent supervision by welfare workers; fatigue study; swimming baths, provision for playgrounds and recreation; care of women before and after childbirth; study and preventive measures for skin diseases; isolation camp: investigations as to lighting and eye strain. In a book entitled "Medical Ethnology," now for sale in England, are discussed conditions suitable for life in the tropics and temperate zones for different races who have migrated into these zones, and it shows the different effects of tropical light on individuals, acting on their nerves, and through nerves on the whole organism, necessitating different conditions of food, clothing, protection of skin, and so on. Attempts will be made to associate workers themselves on committees, and to treat welfare as men's right, and not favour or policy of employer. It follows that there will be as little of obligatory welfare as possible. There is evidence that problems of the relation of the sexes have been present and have been considered, but there are no records of the method of treatment or of the success achieved.

All these matters are before the directors, and the whole comprehensive scheme which I have outlined has been submitted to them by expert advisers, and will be slowly adopted as opportunity occurs and funds are available.

It may appear that all this is only projected, and assumes the character of an advertisement, if I did not say that it is only after careful thought that I have dwelt at such length on these proposals, feeling that comprehensive welfare work must be included in all industrial enterprise after the war. The directors are alive to this, and desire that India may be at least co-equal with Western development, and as the scope of my paper embraces the effect of the Tata works upon industrial India, so important a factor should not be omitted.

It is highly important that due attention be given to sanitation, and at present sewage is treated in septic tanks. Careful investigation is being made into the comparatively new activated sludge system, and this will be shortly tried at Sakchi. The method consists in aerating the sewage by diffusion of air, which stimulates the bacterial action during its passage through several hundred feet of conducting channels, in

which the diffusers are placed, and subsequently its retention in a settling tank in which the flocculent matter is deposited and a clear effluent flows away, the sludge being subsequently dried and sold for fertilising purposes.

It may now be fairly conceded that the establishment of an industry so comprehensive in character must have far-reaching effects upon the development of the country. The railways of a country are indicative of its progress and prosperity. Already many millions of tons are annually borne upon tracks laid with Tata rails, and considerable extensions are projected so soon as the war terminates. In the near future waggons will be built at Sakchi from Sakchi steel, and transport raw material from the various sources to the steelworks, and thence to the seaboard or other destination.

The coal first coked to supply blast furnace requirements will yield tar for fuel and road-making; pitch for coating pipes, making briquettes and caulking purposes; sulphate of ammonia for fertilisers; benzol for explosives and traction purposes; toluol for munitions or blasting agents; naphthalene for disinfectants; not to mention anilines and dyes. It is expected that 2,250,000 gallons of benzol will be produced annually, part of this being directed to the manufacture of dyes, while a large quantity will be available for motor traction, and retailed at prices comparable with that of petrol will popularise the use of motor-cars and lorries more rapidly than has hitherto been the case. It is also quite feasible that motor vehicles may be manufactured as one of the subsidiary industries at Sakchi. Bazaars will dispose of Sakchi enamel ironware, cutlery and other hardware, buildings framed with Tata sections and roofed with corrugated sheets. The technical institute and research laboratory, which will educate chemists and engineers primarily for service at the steel works or subsidiary companies, will, no doubt, furnish skilled scientists for other Indian undertakings. Indian scholars above the average in social position and intellect may be attracted by the educational advantages at Sakchi, and thus include in the scientific professions the superior type of Indian who has hitherto confined himself to the professions of law, medicine, or commerce.

The proximity of a research laboratory and technological institute, contributing data and operating staff on more favourable terms than are demanded by Europeans, will prove factors of great importance to the potential investor, and, on the other hand, the existence of many diverse manufactories grouped round Sakchi will afford opportunities of practical shop experience to the students.

The chairman of the Tata Iron and Steel Company, Sir Dorab Tata, in his speech at the annual meeting of the Company last October, remarked: "We also contemplate to erect at Sakchi a research laboratory for metallurgy and chemistry, and your directors are considering whether they should not approach the Industrial Commission and Government of India with a view to making this laboratory a central national research laboratory in that part of India."

It is reasonable to suppose that after the conclusion of the war many investors will be attracted by the achievements of the several Tata undertakings to avail themselves of the Tata cheap power and semi-products, and initiate other industries which our investigations record as offering a good return on investment.

Although we devoutly hope that in our lifetime we may not be again confronted with the imminence of war, the potential value of this great steelworks must not be lost sight of, for an equipment which in times of peace will supply forgings and castings for ships, locomotives, or other industrial purposes, could, if the need arose, produce guns, shells, explosives, and all the essentials of warfare, by the utilisation of the resources of the country, both material and personal. The value to the Empire of such an arsenal will, I think, be readily admitted, and, should passage through the Suez Canal be cut off, would prove of great value in securing defensive equipments in the East. The success of the Tata Iron and Steel Company with capital subscribed by Indian financiers independently of any foreign aid, and to a considerable extent drawn from profits made in the Bombay cotton industry, inspired confidence in the ranks of Indian investors, whose subscriptions to the Tata Hydro-Electric Power Supply Company were promptly forthcoming, and similarly the capital for a new hydro-electric works, the Andhra Valley Power Supply Company, which is now under construction.

The existence of well-paid regular employment for the aborigines of the Sakchi district means considerable saving to the Government in expenditure on famine relief measures, and the steel companies' contribution to the revenue of the country for the year ending June, 1916, amounted to £130,000, which does not include other receipts from the population of 25,000.

Thus a portion of the vast and hitherto unex-

ploited wealth of India is being made productive. The profits of industry are realised and reinvested in new industrial undertakings. The status of the worker is being improved, and the influence of these factors upon the social and economic prosperity of the country is already widely appreciated, and will, as years go by, prove a determining feature in the industrial progress of India.

As the small pebble stirs the peaceful lake,
The centre mov'd, a circle straight succeeds,
Another still, and still another spreads,
Friend, parent, neighbour first it will embrace,
His country next; and next all human race.

The paper was illustrated by a series of excellent kinema views and lantern-slides.

DISCUSSION.

THE CHAIRMAN (Lord Lamington) said the paper was exceedingly interesting, in fact, a monumental record of an achievement usually associated in this country with blackness and dirt, but in the present case almost transformed into a fairy tale or a romance under the Indian skies. It was very satisfactory to know that the Indian Empire not only produced all those things that the Orient was famous for, but also had a wealth of iron ore which would make the mouths of some men interested in the iron trade water to think of. To him the most interesting feature of the paper was the evidence it afforded of the remarkable co-operation that had existed in bringing the enterprise to such successful fruition. It was a matter of pride to think that in our Indian Empire, under our great system of organisation and administration, a Parsee gentleman should have the enterprise and confidence to develop so great a work. He (Lord Lamington) was glad to think that our American kinsmen had been participants in the building up of so great an industrial achievement.

MR. ARTHUR BALFOUR, of Sheffield, said the meeting was greatly indebted to the author of the paper for the very lucid way in which he had described the wonderful plant which had been erected in India. Those who had to do with steel works would well know the difficulties which had to be overcome, even when skilled labour and technical help were available, as in this country; but the difficulties in India, increased by the war, must have been enormous, and great perseverance and determination had been shown by those who brought the great Tata works into being. The Company was to be congratulated on having added such a magnificent steel plant to the productive capacity of the Empire. The question arose as to what was to become of the steel that was produced, having regard to the fact that large plants in this country were also being quadrupled. But he was convinced that, with a lasting peace and security on which people could base enterprise in the future, there would be no difficulty at all in absorbing the whole of the iron and steel that could be possibly produced by this or any other country. The great thing to be aimed at both in India and in the Colonies was a large extension of railways, and that alone would absorb enormous quantities of steel. Then the shipbuilding programme of this country, to place us in the position that we were in before the war, would also absorb a very large quantity of steel. The war had shown how absolutely essential it was that the Empire should be independent in the matter of supplies of steel, and everyone would be only too glad to find Australia, New Zealand, India, or any other part of the Empire, assisting in producing such quantities of material that in future we might not find ourselves in the position we were in before the war. He remembered well the day when the Tata Company asked the Sheffield University to spare Dr. M'William to go out to India. He was a very valuable experimentalist at the University, but it was immediately decided that if anything could be done to develop industry in India the University should let him go at once, and he thought Dr. M'William had been of great assistance to the enterprise.

MR. C. H. B. BURLTON said it was a matter of very great importance that the mineral resources of India should be exploited more than they had been. It seemed to him to be a reflection on the Government of India that such vast wealth hitherto had remained unexploited, and that it would not have been exploited at all if it had not been for private enterprise, to which everything had been left with the exception of the agricultural resources of India, which had been fully developed by the huge irrigation works that had been constructed. With regard to the case of Joseph Heath, it was a very pathetic one, and it appeared that the East India Company let him down rather badly. He was a retired Indian civilian, and no doubt fully expected to benefit himself, but he would certainly have benefited the country at the same time if his enterprise had proved successful. As it was, he failed, but he deserved a better fate than having been allowed to die penniless. His enterprise was afterwards worked by the East India Company, and also the Government of India, for about twenty-one years. There was also another iron works which was a private enterprise; it failed, and the Government of India formed it into the Bengal Iron and Steel Company. That might also have come to grief if it had not paved the way for the third enterprise —that of Messrs. Tata, who were far too dogged and determined in every way to be overcome by any difficulties. They had prospered, and they deserved the success they had attained. The country must be very grateful to them for all the

benefits those large works had conferred, irrespective of any benefit Messrs. Tata might have derived themselves. The Company were dependent on the resources of India, but he noticed, from what the author said, that some million bricks were imported in about four years. He did not know why fire-bricks should be imported into India when the minerals were there for making them. He understood that Messrs. Tata were using their own magnesite deposits in Mysore for the making of the fire-bricks. Although the material no doubt was excellent, it was scarcely possible there could be enough minerals derived from Mysore to supply the vast quantity of bricks required, but there were other deposits, and if the Government of India would support private enterprise by giving a market for the sale of the goods those deposits could be developed. If people who owned deposits of magnesite or any other mineral, could turn it into the finished brick in the country, it would be a great advantage to the country, as well as to the individuals themselves, and stop the pernicious custom which at present prevailed of importing goods, which very likely had gone out of India to England and returned to India for utilisation. The exploitation of the deposits in India would result in furnishing sufficient material for the manufacture of fire-bricks and the lining of basic furnaces, and be very important in the present time of war, and of great advantage to our armies in Mesopotamia.

Mr. Alan A. Campbell Swinton, F.R.S. (Chairman of the Council), in proposing a vote of thanks to the author of the paper, said that anyone who had had to do with industries of any description could only admire the way in which the problem of the Tata works in India had been solved by Messrs. Tata: it was a most wonderful performance that such large works should have been established practically in the jungle. He was sure all who had heard the paper wished the Company every success, and hoped that their example would lead to the establishment of similar and other works in different parts of India.

Sir M. M. Bhownaggree, K.C.I.E., in seconding the motion, said the author had dealt with the subject in such a way that even those who had no technical knowledge had a good idea of what the Tata works were like. The paper fittingly paid a tribute to the memory of a great man, Mr. Jamsetji Tata. He did not think that Mr. Tata during his life obtained that recognition which was his due, either from the Government or from his own people. But to-day the seeds he had sown were giving a developing crop year by year, and people were beginning to realise what a great thing he had done for India. Personally he had a great reverence and admiration for those who conferred benefits on India, and he did not hesitate to say that Mr. Tata was perhaps the greatest benefactor of India and her people. He had introduced into the country an institution which would be far-reaching in its effects and of the greatest importance. If the admirable paper of Mr. Tuckwell, with its instructive illustrations, could be reproduced before Indian audiences in all parts of India—and even perhaps before audiences of certain Government officers who had the educational destiny of India in their hands—it would teach a great deal and point out the direction that should be followed in the education of the rising generation of India, in order that India herself might benefit, and that her connection with the British Government and British rule might be permeated with a sense of contentment, which he was perfectly sure the present situation of education did not inculcate.

The resolution was carried unanimously.

Mr. H. M. Surtees Tuckwell, in reply, said he was sorry that one misunderstanding had occurred. The time of which he spoke, when large quantities of bricks were brought in, was that when the works were first being built, when the work was actually being carried out in the jungle, and when the materials had not been carefully analysed and the resources were not properly understood. When war began, the Company was importing a certain number of bricks by permission of the Government, but recently they had had a cable from India to say that the Company were now entirely independent of English resources, and that the requirements of 40,000 bricks would all be made of Indian material in Indian factories, either through or in connection with the Tata steel works.

The Hon. Sir Charles A. Parsons, K.C.B., F.R.S. (Vice-President), in thanking Lord Lamington for taking Lord Sydenham's place, said that, as a former Governor of Bombay, it must have given him immense pleasure to see the great development which had occurred. Now that our Colonies and Dependencies had rallied round the Mother Country in her time of trouble, it was for the British people to give every support to any development in the Colonies and Dependencies like the one described in the paper, because such a development would not only be to the benefit of the Colonies and Dependencies, but add to the strength of the Empire.

The Chairman, in returning thanks, said the paper was one of the most remarkable he had heard read for a long time, and he thought the whole conduct of the enterprise reflected the greatest credit on those who had conducted it so successfully. With regard to rendering the Empire independent of outside resources, nobody could gainsay the necessity of that for one moment. He thought that in the past the Government of India had rather checked than encouraged private enterprise, but if they would forego their jealous

anticipations he was confident that the Indian people would come forward and invest their money to the profit of themselves and the great benefit of the country and of the whole of the Empire. Mr. Tuckwell had referred to what had been done in the way of encouraging co-operation and thrift amongst the workers, and perhaps it afforded a lesson that might be learned by some of our Government Departments at home in the present crisis. Mr. Tuckwell was to be congratulated not only on having read a very remarkable paper, but also on the fact that he himself was intimately connected with such a wonderful enterprise. It was an enterprise of a monumental character, and would no doubt form a turning-point in the transition of India from a great agricultural country to a manufacturing country.

The meeting then terminated.

SIR BRADFORD LESLIE, K.C.I.E., writes:—I was much interested by Mr. Tuckwell's admirable paper, having been an original director of the Barakar Ironworks. In 1916, in suggesting the construction of the Mesopotamia Railway to the Secretary of State for India, I said I had no doubt that rails could be obtained from the Tata Company, and I am glad to find that rails of their manufacture are now in use in that railway. I note that the Land Acquisition Act has been enforced by Government on behalf of the Tata Company; this the Government refused to do for the original Barakar Ironworks Company, because it was a private enterprise. Post-war sea freights will be greatly reduced; the Railway Board should require the companies to quote minimum rates to enable Tata products to compete with imported steel and iron at Karachi, Bombay, Rangoon, and the Straits. Tata should manufacture wheels and axles and waggons of standard type complete, including bogie stock for 60-feet rails, which are difficult to load and discharge at seaports. Saving fish-joints, long rails are economical, and in handling them Tata would have the advantage over shipping. What arrangements have been made to purchase and work up worn rails and other scrap steel? Formerly scrap rails were purchased at Rs. 25 per ton for export to the United States. Towards the end of the year 1870 I introduced the use of scrap rails for structural purposes in station buildings, and even as material for railway bridges. I also used them in constructing warehouses and factories for private firms, and in 1880 for constructing the East Indian Railway offices in Dalhousie Square. This created a market for scrap rails, and prices rapidly rose to Rs. 60 per ton, but heavy rail sections are not economical for building construction; it would be preferable to re-roll 80 lb. scrap to 56 lb. metre gauge rails, thus helping to fill up the deficiency caused by the war, or to cut them up and re-roll them as bar iron of more economical sections—this is a direction in which the Tata Company might do useful and profitable work. Most important of all is afforestation, to temper solar heat and improve rainfall; 118 degrees in the shade is a high temperature, and if the country were well wooded I am confident such a temperature would be very rare. When the East Indian Railway locomotive workshops at Jamalpur were first planned, the hills at the back were beautifully wooded; unfortunately the timber was not protected, the trees were felled, cut, and hacked for building and firewood, and soon nothing remained but bare rocks, which are reverberatory furnaces, absorbing sun heat by day and radiating it by night; the soil was washed away and it was found impossible to get the trees to grow again. Undergrowth and jungle should be cleared; it is a source of malaria, and is often the cause of the spread of forest fires. The villagers should be encouraged to graze their cattle and goats, keeping down rank vegetation as much as possible; but wherever trees will grow, trees should be planted, tended, and protected while young from goats and cattle, and all growing trees should be preserved. During sunshine every tree, through its leaves, is absorbing solar heat from the atmosphere and converting it into fixed carbon, charcoal; bind a wire round the trunk of a tree, in a year it will be found tightly strained and cutting into the bark. Not only the trunk and branches but the roots are by sun heat rendered latent and reproducible by burning. Thus forests temper atmospheric heat and cause precipitation from saturated air which would otherwise pass over bare ground from which heat is always radiating day and night. The value of forests is generally estimated in terms of timber produced. I am confident that their absorption of solar heat that would otherwise be radiated, though indirect, is in India really of far greater value than the timber produced. Of course, the Forest Department should understand and attend to all this, but my experience of Government Departments is not altogether satisfactory; and if the Tata Company realise the soundness of my observations I recommend them to take up afforestation, especially on the side of their location next the prevailing winds, and give it their earnest and intelligent attention.

MR. TUCKWELL writes, with reference to the above letter:—Sir Bradford Leslie's suggestion that the Tata Iron and Steel Works should manufacture wheels, axles and standard waggons complete has long had consideration from the directors; and the extensions, as I mentioned in my paper, will include a waggon factory, and probably embrace the manufacture of wheels and axles as soon as circumstances make it desirable. The purchase of scrap in large quantities is contemplated, to economise the use of pig-iron in the furnaces, and I imagine that the price of seconds for several years will be high enough to warrant worn rails being re-rolled. For several years our consulting engineer has utilised scrap rails for structural purposes, and we have shipped out from England

special rolls for re-rolling 90 lb. waste rails down to 30 lb. Sir Bradford Leslie's suggestions in regard to afforestation are most interesting, and will be forwarded to India for the attention of our Directors and consulting engineer.

CORRESPONDENCE.

WATER POWER IN GREAT BRITAIN (WITH SPECIAL REFERENCE TO SCOTLAND).

Mr. Newlands has rendered an invaluable service to the country by drawing attention to the vast resources of water power available in the United Kingdom and Ireland. The data given in his paper, which he must have taken endless trouble to collect, fully corroborate what I had stated in an article on "Scottish Water Power Development and its Possibilities," which appeared in the *Engineering Review* of September 15th, 1911.

That it is necessary, now more than ever, to enlighten the public on the importance and the real value of the water power available in this country, and to overcome the prejudice against its utilisation, prevalent even among engineers, is proved by the fact that I was told in the discussion of my paper on water power, read before the Institution of Electrical Engineers in 1895, that there was no water power in this country worth considering, especially on account of the irregularity of the water-supply. I have been able to show, and prove by numerous turbine installations with low and varying falls and a varying water-supply, for which I am responsible, that a constant and good water power can be obtained under such conditions. I was told that a water power which is varying, would have to be supplemented during part of the year by artificial power, generated by steam, oil or gas, at an increased capital outlay which would render such a mixed plant unremunerative. It seems to be entirely forgotten that the initial outlay for such auxiliary power forms a relatively small part of the total capital outlay, while the low annual expenses of the hydraulic plant are only slightly increased by the temporary use of auxiliary power required to keep up the supply to the demand of power. An absolutely constant power can hardly be found anywhere, and wherever it has been utilised to its full capacity it has been found necessary to add steam plant to comply with the increasing demand, and always to the advantage of the undertaking. I am informed that even at the Niagara Power Plant steam power is being added.

In order to ascertain the value of a water-supply as a source of power, and the extent to which it may be used for that purpose, it is not sufficient to go only by the records of the annual rainfall and the catchment area, which have often been misleading, but regular gaugings should be taken of any river likely to be utilised. The Swiss Government has for years, through its hydrographic department, taken such gaugings and is, therefore, in a position to state with accuracy the amount of power which we can obtain from our watercourses.

According to statistics published in 1912, the power obtainable in Switzerland is—

834,000 h.p.	for 12	months.
1,403,000	,, 9	,,
2,557,000	,, 6	,,

It may be of interest to know to what extent this power has been utilised—

Minimum	power on January 1st, 1914,	303,118 h.p.
Average	,, ,, ,, ,,	517,341 ,,
Maximum	,, ,, ,, ,,	775,550 ,,

In the development of water power the cost is, of course, the first point to be considered. It is generally held that high-fall plants are cheaper than medium or low-fall plants. This is correct only as far as the cost of the turbines is concerned, but long pipe-lines often make the cost of high-fall plants even more expensive than medium-fall plants of the same capacity.

With regard to the economical point of view, the noteworthy fact may be mentioned that in Westphalia, the centre of the German coal industry, whole valleys have been closed by large dams forming artificial lakes for the threefold purpose of regulating the flow of water for navigation of rivers, to prevent flooding, and to obtain power.

ALPH. STEIGER, M.Inst.C.E.

With reference to the important paper by Mr. Newlands, published in the *Journal* of January 25th, I should like to call attention to the extent to which our knowledge of the available water power depends on observations of rainfall. There are, I believe, no records of continuous stream-gauging in this country which have been continued long enough to furnish directly the average flow of any river. There are, however, many hundreds of long rain records which suffice for determining the average rainfall of which stream-flow is an ascertainable function. When, in 1897, the Royal Society of Arts presented the Albert Medal to Mr. G. J. Symons, in recognition of his work on founding and carrying on the British Rainfall Organisation, there were just over 3,000 records being kept by voluntary observers, and published annually at their own expense in *British Rainfall;* there are now more than 5,000 such records, enabling a fuller account to be given of the rainfall of the British Isles than of any other country in the world. Unfortunately observations are most scanty in just those remote and mountainous districts, which are of most importance for water power. Had the series of observations at Highland railway stations which Mr. Symons induced the Company to start in 1873, only been continued, we should now be in possession of numerous long records, the want of which can never be fully made good. I earnestly hope that all who have the welfare of the Highlands at heart will be moved by Mr. Newlands' paper to set about the immediate establishment of new rain-

fall stations. The observations are easy, the instruments cheap, even in war time, and I feel strongly that the advantages of voluntary co-operation outweigh those of formal Government control. All information as to rain gauges and the methods of observing will be supplied gratuitously on application to me.

HUGH ROBERT MILL,
Chairman of Trustees and Director
British Rainfall Organisation.

OBITUARY.

SIR JOHN WOLFE WOLFE-BARRY, K.C.B., LL.D., F.R.S.—By the death of Sir John Wolfe-Barry the Society loses one of its most distinguished Fellows, and the Council one of its ablest and most efficient members. His death occurred on January 22nd, at his residence, Delahay House, Chelsea Embankment, at the great age of eighty-one, as he was born in December, 1836, in London. He was the fifth and youngest son of the eminent architect, Sir Charles Barry, R.A., who also was a member of the Society, which he joined in 1836. The family was a remarkable one, for of Sir Charles's five sons, four achieved distinction in their several professions. The third son, Edward, "completed his father's work, and succeeded to his reputation." He, like his father, was a Royal Academician. The eldest, Charles, also followed his father's profession, and acquired a considerable practice, and became President of the Royal Institute of British Architects. Alfred, the second, became Bishop of Sydney and Primate of Australia.

John Wolfe Barry (he combined his Christian name of Wolfe with his surname, and became Wolfe-Barry in 1898) was educated at Trinity College, Glenalmond, where his brother Alfred was Sub-Warden, and at King's College, London. He was articled to Sir John Hawkshaw, under whom he served as assistant resident engineer in the construction of Cannon Street and Charing Cross railway stations, with the two great bridges leading to them. In 1867 he set up on his own account, and soon laid the foundations of a large and extensive practice, which developed on lines certainly influenced by the important works on which he was employed in his youth. Throughout his long and successful career it was in dealing with transportation questions that his great reputation was acquired, and it was the construction and development of railways, roads, canals, harbours and docks that occupied practically the whole of his attention as a professional engineer. The two great works with which his name is most closely associated in the public mind are probably the London Tower Bridge and the South Wales Barry Docks, but these are only two on the long list of important works carried out by Sir John Wolfe-Barry, or under his advice, in the United Kingdom as well as in India, Africa and China. This brief allusion to his professional life-work must suffice for these columns, but it may be permitted to refer those who desire fuller information to the record which appeared in *Engineering* of last week, where his professional career is treated in full detail.

Mr. Barry, as he was then, joined the Society in 1890. In 1894 he was elected on the Council, and on it he served continuously till his death, with only one short break in 1910. In 1898 he became Chairman of the Council, and the previous year he had received the K.C.B., the C.B. having been given him three years before, after the completion of the Tower Bridge. He availed himself of the opportunity afforded by the two addresses he delivered as Chairman of the Council to bring prominently before the public his views on London transportation. The first of them was on "The Streets and Traffic of London," and the second on "London Communications." In them he worked out a full and comprehensive scheme for improving communication along the main arteries of traffic by facilitating the passage of the two great currents —east and west, south and north—at the points where they crossed. At such points it was proposed that the streams should be led to different levels one over the other, suitable access from one to the other being provided by slightly inclined roadways. The scheme was perfectly simple and practicable, though obviously costly in execution, but it never got beyond the stage of suggestion. After the expiration of his term of office Sir John's interest in the work of the Council in no way declined, for he was a regular attendant up to last autumn.

As Chairman of the Council he became an *ex officio* member of the Governing Body of the City and Guilds Institute, and this led to his devoting much attention to the subject of technical education. Eventually he became Chairman of the Executive Committee of the Institute, and took a leading part in its work, for after he ceased to represent the Society he was continued on the Governing Body of the Institute as one of the representatives of the Goldsmiths' Company. He was for some time on the Court of this company, and in 1912 he served as its Prime Warden. In this capacity, as well as in his chairmanship of the Institute's Committee he was a successor of Sir Frederick Bramwell, one of the founders of the Institute and its first chairman.

His services to education in connection with his own profession, however, go back to an earlier date, for it was largely owing to his influence, and to the stress laid upon the need for raising the standard of qualification for membership of the Institution in his two Presidential addresses (1896 and 1897) to the Institution of Civil Engineers, that its regulations were remodelled and an examination instituted for admission to the initial stage of its membership.

The piece of work on which (apart from his purely constructive engineering works) he probably most prided himself, and the one which must always be associated with his name, was

the establishment of the Engineering Standards Committee. Put briefly, it may be said that the object of this committee is the standardisation of all materials employed in engineering. In 1901 a committee was appointed, at his initiative, by the Council of the Institution of Civil Engineers, to consider the advisability of standardising various kinds of iron and steel sections. The work of the committee was so successful that it soon developed into an important organisation of great influence, which has had a most beneficial effect on the industry, resulting in large economies. The successful work of the committee and its influence on the prosperity of the country formed the subject of the "James Forrest Lecture" delivered by Sir John in May, 1917, and this indeed was probably his last appearance before a public audience.

It will be seen that his professional career extended just over fifty years—from 1867 to 1917—and he continued it with unabated vigour until his last illness, for if during the last few years he had somewhat retired from actual professional work, he certainly did not relax in his many public engagements. His personal vigour and vitality seemed unimpaired, as was for instance shown by the excellent Forrest lecture which, as above stated, he delivered last year. A man of considerable business capacity and shrewd common-sense, he possessed also a singularly genial nature and a very pleasant manner. These qualities gained him a host of friends, as was shown by the crowd which filled St. Margaret's Church, Westminster, at the funeral service last Saturday. If he had outlived nearly all his contemporaries, he had gained the esteem and the regard of a generation of younger men both in and outside the great profession of which, at the time of his death, he was the admitted and respected head.

Thomas Abercrombie Wilton.—The death of Mr. Thomas A. Wilton took place on January 16th. He was elected a member of the Royal Society of Arts in 1870, and contributed several letters to the *Journal* on subjects connected with Indian and African trade. An eminent accountant, he was one of the oldest members of the Royal Statistical Society, which he joined in 1855. He contributed a number of papers to their Proceedings, and served on their council for many years. For the last twenty-five years he acted as Vice-Chairman of the Inspection Committee of Trustee Savings Banks.

John Scudamore Sellon.—Mr. John Scudamore Sellon died in London on January 16th, at the age of eighty-one. Early in life he entered the firm of Messrs. Johnson, Matthey & Co., assayers and refiners to the Bank of England and Royal Mint, and he took a prominent part in the research work and industrial developments connected with platinum and other rare metals with which the name of his firm is associated. He was also deeply interested in electrical engineering, having been connected with Faure, Brush, Swan, Lane-Fox, and others in their early work in lighting and storage.

Mr. Sellon was elected a member of the Royal Society of Arts in 1882, and on several occasions he took part in discussions on subjects relating to electric lighting.

NOTES ON BOOKS.

The Preservation of Wood. By A. J. Wallis-Tayler, A.M.I.C.E. London: William Rider & Son, Ltd., 1917. 10s. 6d. net.

The subject-matter of this book is opportune to the moment. Timber is at a premium. By not less than 100 per cent. have the prices of imported woods advanced—now steadily, now *per saltum*—since 1914. The demand for home-grown and home-growing timber, mature and immature, has left a mark upon our own plantations that will not readily be effaced. The woods and forests of the world are in course of a lamentable denudation. If, then, in the old days of plenty, the application of some preservative process to wood which was intended for constructional use was recognised as an economic desirability, how much the more is it now, and must it be in the future, a clamant necessity?

In these circumstances, Mr. Wallis-Tayler has done well to draw up this monograph on the history, methods and economics of timber preservation.

In an introductory chapter the author submits a rapid sketch of the evolution of its practice, from the early days of Egypt and Rome, and the use of bitumen and the oils of olive, cedar and spikenard, down to the end of the eighteenth century, and the introduction, at the instigation of Congreve, of the all-important creosote processes. From that period he follows, with considerable detail, the numerous investigators who, throughout the nineteenth century, pursued many and diverse paths of experiment and practice in England, on the European continent and in America.

Upon this follows a short study of the natural history of the enemies of timber: fungoid, and low in type, as in the "wet" and "dry" rots; animal, and higher in the scale of organisation, as in teredo and the ants. Here the gain arising from the use of appropriate preservative processes is well brought out, not only in the text, but by a series of illustrations showing the ravages to which untreated wood is subject.

Thence we pass to the consideration of the methods, natural and artificial, employed in the seasoning of timber; a stage through which, save in the paramount emergency of war, all woods must pass before preservative treatment can be applied with profit. A number of the most recent and approved forms of drying plant, such as are now in use in this country and abroad, are clearly described and figured; and the physical factors concerned in their employment are dealt with through the medium of a graph and a succession of numerical tables.

And thus we reach the heart-wood of the matter: the theory and practice of the application of chemical substances to seasoned timber with a view to increasing the duration of its soundness when in constructive use.

It is not possible, within the limits of a short review, to follow the author through the ramifications of this subject. Sufficient it must be to say that, after an admirable exposition of the theories and hypotheses underlying the different methods that are in practical employment, and dividing the latter under the two main heads of "open tank" and "pressure" systems, he describes the creosoting processes of Bethell, Rueping, Lowry and Curtis-Isaacs; the zinc-creosote processes of Rutger and Card; the creo-resinate process of the United States Wood Preserving Company; the saponified creosote process of Collins; the early bichloride of mercury process of Kyan; the zinc-chloride process of Burnett; the sulphate of copper processes of Boucherie and Hasselman; the saccharine process of Powell; and many others.

A succeeding chapter deals with some fifteen proprietary preparations which are available for use either within the body of the timber or as an external coating. The next treats of the absorption limit, and of the increased durability of preserved wood. Another concerns itself at some length with the application of fire-proofing and fire-retardant processes. And the last is devoted to the all-important subject of the cost of the various preservative treatments. The book comes to an end with some thirty-seven pages of formulæ, tables and memoranda, to which—one ventures to suggest—a Schedule of Processes based on the ratio

$$\frac{\text{Increased durability of timber}}{\text{Cost of preservative treatment}}$$

would be a useful addition.

A work prepared in these days of stress and hurry can hardly fail to show a few blemishes. One is inclined to quibble with the statement that ". . . the gases evolved . . . produce fungi . . ."; and a lengthy footnote on page 19 is, through some accident, unintelligible as it stands. Such small faults will, doubtless, be amended in the next edition.

Mr. Wallis-Tayler is to be congratulated on the production of an eminently useful book. G. E.

The Industrial and Artistic Technology of Paint and Varnish. By Alvah Horton Sabin, M.S. Second Edition. New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 16*s.* 6*d.* net.

The use of varnish dates back to very early days, the oldest in existence being probably that used on wooden mummy cases made in Egypt some twenty-five centuries ago. This appears to be a solution of resin in an essential oil, and it is so durable that it has stood exposure to the air all this time, and still looks well. Mr. Sabin has also discovered that the value of white lead has been properly appreciated for almost as long, for he refers to a passage in Xenophon's *Economicus*, where one of the speakers mentions that his wife was at one time in the habit of rubbing it into her skin to make her face look white, and then dyeing her cheeks and lips with alkanet to make them red.

From this it will be seen that the author has not neglected the early history of his subject, which is summed up in a short but interesting introductory chapter; but his aim is "to give a correct general outline of the subject of paints and varnishes, with a brief account of their modern use and of the principles which are involved in their fabrication and application." The book is divided into twenty-four chapters, of which three are devoted to linseed oil. This second edition is nearly a third larger than the original, and among the most important additions is the section on the use of tung-oil in varnish-making. This, says the author, has entirely changed the character of cheap and medium-priced products. Varnishes containing it dry with a rapidity and hardness unknown before; and they also possess remarkable water-resisting properties.

The volume is written in a careful and scholarly style, and the opinions are based on the long personal experience of the writer.

A Handbook of Elocution. By Edward Minshall. London: John Murray. 1*s.* 6*d.* net.

It ought hardly to be necessary to insist upon the advisability of teaching children to speak their words clearly, but one notices among many of the young people of to-day a tendency to a slip-shod enunciation which cannot but be disadvantageous to them if they have to play parts of any importance in later life. This little handbook has been compiled for the benefit of those who are victims of bad elocutional habits formed in their youth, and who desire to correct their faults. It is the work of one who has had long experience in teaching elocution at the City of London College, and it will be found full of sound advice likely to be helpful to those for whom it is intended.

GENERAL NOTES.

British Coal in 1916.—The total value of the minerals raised in the United Kingdom in 1916 amounted to £214,034,524—an increase of £43,576,266 as compared with 1915. The total output of coal was 256,375,366 tons, and the value £200,014,626—an increase in the output of 3,169,285 tons, and in the value of £42,183,956, on the figures for the preceding year. The quantity of coal exported, exclusive of coke and manufactured fuel and of coal for the use of steamers engaged in foreign trade, was 38,351,553 tons, of which France received over 17½ million tons, Italy nearly 5¾ million tons, Norway over 2¼ million tons, Denmark over 2¼ million tons, Spain over 2 million tons, Sweden over 1½ million tons, and the Netherlands over 1¼ million tons.

GROUNDNUTS IN THE UNITED STATES.—The value of the groundnut crop in the United States, according to *Agriculture*, has risen from twelve million dollars in 1908 to fifty-six million dollars in 1916. By slight adjustments of machinery cotton-seed mills can be used for crushing the nuts; but an increasing proportion of the crop is being used for food purposes in the uncrushed state. Experiments under the auspices of the Chemical Bureau of the Department of Agriculture are said to hold out promise of the production from groundnut meal of a bread equal in nutritive value and palatability to wheaten bread.

SCANDINAVIAN AIR TRAFFIC.—At a recent meeting of the Aeronautical Society in Stockholm, Captain Dahlbeck gave a survey of aeroplane traffic in Sweden. Denmark has no air traffic society as yet, but a large new factory for aeroplanes is in full swing. Denmark is taking an interest in comprehensive international schemes—such as England-Denmark-Sweden and Germany-Sweden-Norway routes. In Denmark the legal side of the question—the protection of national territory and the granting of concessions—is attracting a good deal of attention at present.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

FEBRUARY 6.—WM. FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines, "The Development of Mineral Resources of the Empire." SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., will preside.

FEBRUARY 13.—LORD LEVERHULME, "The Relations between Capital and Labour — Reasonable Hours, Co-partnership, and Efficiency."

FEBRUARY 20.—MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." SIR ASTON WEBB, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

FEBRUARY 27.—SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

MARCH 6.—A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 13.—PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The ARCHBISHOP OF CANTERBURY will preside.

MARCH 20.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

Dates to be hereafter announced :—

MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

PERCY SHUTTLEWOOD, Ministry of Food, "The Food Situation in Germany."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m. :—

FEBRUARY 14.—SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Hide Trade and Tanning Industry of India." The RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 14.—

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m. :—

FEBRUARY 5.—C. DU PLESSIS CHIAPPINI, Trades Commissioner for the Union of South Africa, "The Industrial Resources of South Africa."

The RIGHT HON. VISCOUNT GLADSTONE, G.C.B., G.C.M.G., G.B.E., will preside.

MARCH 5.—

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, "High Temperature Processes and Products." Three Lectures.

Syllabus.

LECTURE III.—FEBRUARY 4.—*Products and their Uses.* Artificial graphite for various purposes—Carborundum for abrasion and refractory purposes—Alundum and silica for chemical apparatus and refractories—Calcium carbide for making acetylene—Pure metals by thermit processes—Siloxicon and other silicon—Carbon compounds for refractories and thermal insulators—Aloxite and its uses.

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 4...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. C. R. Darling, "High Temperature Processes and Products." (Lecture III.)

Chemical Industry, Society of (London Section), at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Meeting of London Chemists to consider the formation of a British Association of Chemists.

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. W. A. Simmons, "Food Control as affecting Agriculture."

Royal Institution, Albemarle-street, W., 5 p.m. General Monthly Meeting.

TUESDAY, FEBRUARY 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. C. du Plessis Chiappini, "The Industrial Resources of South Africa."

Röntgen Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "The Problems of British Anthropology." (Lecture I.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. The Hon. Sir Francis J. E. Spring and Mr. H. H. G. Mitchell, "The West Quay of Madras Harbour."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. D. S. Smith, "Exhibition of slides of Reptiles taken in the Gardens." 2. Mr. T. E. Whitehead, "Notes on the Dingo in Australia." 3. Professor B. L. Bhatia and Baini Prashad, "Notes on the Skull of *Rana tigrina*." 4. Mr. G. A. Boulenger, "Description of a new Snake of the genus *Oligodon*, from Upper Burma." 5. Dr. R. Broom, "On a new and a rare Species of the Golden Mole (*Bematiscus*)."

WEDNESDAY, FEBRUARY 6...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Professor W. Frecheville, "The Development of the Mineral Resources of the British Empire."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Geological Society, Burlington House, W., 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 5 p.m. 1. Annual General Meeting. 2. Mr. A. E. Parkes, "A modified Acetic Acid Reagent for Valenta Tests." 3. Messrs. E. R. Bolton and C. Revis, "Oiticica Oil—a new drying oil."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Mr. J. G. Turner, "What Steps are possible to Improve the Teeth of the Nation?"

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m. Dr. R. Munro, "Scottish Crannogs: their Structure, Distribution and Chronological Range."

THURSDAY, FEBRUARY 7...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. The General Secretary, Two Bibliographical rarities of the Society's Library: (*a*) "Cupani, F., Panphyton siculum, 1713"; (*b*) "Du Gort, J. & P., L'Histoire et Pourtrait des plantes. Lyon, 1561." 2. Mr. H. P. Guppy, "Plant Distribution from the Standpoint of an Idealist."

Chemical Society, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Napier Shaw, "Illusions of the Atmosphere: the Travelling Vortex and the Cyclonic Depression." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. F. M. Duncan, "Curiosities of Crustacean Life."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. (Kelvin Lecture.) Professor M. Maclean, "Kelvin as a Teacher."

FRIDAY, FEBRUARY 8...Royal Institution, Albemarle-street, W., 5.30 p.m. Principal E. H. Griffiths, "Science and Ethics."

University of London, Slade School of Fine Art, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture IV.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m. Annual General Meeting.

SATURDAY, FEBRUARY 9... Royal Institution, Albemarle-street, W., 3 p.m. Mr. M. P. H. Loyson, "The Ethics of the War." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes in the City of Westminster.—February 1, 1918.

No. 3403. FEBRUARY 8, 1918. Vol. LXVI.

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society of Arts

CANTOR LECTURES.

A full list of the Cantor Lectures which have been reprinted from the **Journal** and published separately may be obtained on application to

THE SECRETARY, John Street, Adelphi, London, W.C.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, or the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. RIALL SANKEY, R.E., M.Inst.C.E. (1912.) Price 1*s*.

Aeronautics. Three Lectures. By Prof. J. E. PETAVEL, D.Sc., F.R.S. (1913.) Price 1*s*.

Surface Combustion. Three Lectures. By Prof. WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s*.

Motor Fuel. Three Lectures. By Prof. VIVIAN B. LEWES, F.I.C., F.C.S. (1915.) Price 1*s*.

Coal and its Economic Utilisation. Three Lectures. By Prof. JOHN S. S. BRAME. (1917.) Price 1*s*.

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s*.

Journal of the Royal Society of Arts.

No. 3,403. VOL. LXVI.

FRIDAY, FEBRUARY 8, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, FEBRUARY 13th, at 4.30 p.m. (Ordinary Meeting.) LORD LEVERHULME, "The Relations between Capital and Labour—Reasonable Hours, Co-partnership, and Efficiency."

THURSDAY, FEBRUARY 14th, at 4.30 p.m. (Indian Section.) SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Indian Hide and Leather Trade." The RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, February 4th, MR. CHARLES R. DARLING, A.R.C.Sc.I., F.I.C., Lecturer in Physics, City and Guilds Technical College, Finsbury, delivered the third and final lecture of his course on "High Temperature Processes and Products."

On the motion of the Chairman, SIR HENRY TRUEMAN WOOD, a vote of thanks was accorded to Mr. Darling for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, February 5th; The RIGHT HON. VISCOUNT GLADSTONE, G.C.B., G.C.M.G., G.B.E., in the chair. A paper on "The Industrial Resources of the Union of South Africa" was read by MR. C. DU PLESSIS CHIAPPINI, Trades Commissioner for the Union of South Africa.

The paper and discussion will be published in the *Journal* of February 15th.

NINTH ORDINARY MEETING.

Wednesday afternoon, February 6th; SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., in the chair. A paper on "The Development of the Mining Resources of the Empire" was read by MR. WM. FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines.

The paper and discussion will be published in the *Journal* of February 22nd.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

EIGHTH ORDINARY MEETING.

WEDNESDAY, JANUARY 30th, 1918; SIR ARTHUR D. STEEL-MAITLAND, Bt., M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barron, William Alfred, M.Inst.M.M., London.
Bedwell, George Champion, Cambridge.
Brander, James, Bristol.
Britton, William, M.I.Mar.E., Aden.
Challen, Charles Hollis, London.
Elliott, Sir Bignell George, K.B.E., London.
Guild, John, Honolulu, Hawaii.
Hearn, John Edward, Luton.
Hind, John, Kohala, Hawaii.
Lewis, A., Honolulu, Hawaii.
Lidgate, Anthony, Hamakua, Hawaii.
Lucas, Harry, Birmingham.
Quittenton, Charles Henry, Warlingham, Surrey.
Searle, Richard Charles, Leicester.
Sen, Nirmul Chunder, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Armstrong, Lieut.-Colonel J. A., R.E., London.
Ashford, John, M.I.Mech.E., India.
Brecknell, Henry Edwin Frank, Bristol.
Brown, Lieut.-Colonel F. Leslie, D.S.O., South Africa.
Bunker, George R., Yonkers, New York, U.S.A.
Butcher, Arthur Douglas Deane, Egypt.
Butler, William, Pittsburg, Pennsylvania, U.S.A.
Carnt, Engineer-Commander Albert John, R.N., Peterborough.
Carruthers, Engineer-Captain David John, R.N., Sevenoaks.
Dommett, Lieutenant William Erskine, R.N.V.R., Bedford.
Geejgarh, The Chief of (Thakur Sahib Kushal Singh), India.
Gill, Harry, Kinlochleven, Scotland.
Graham, Alfred H. Irvine, Assoc.M.Inst.C.E., Surbiton.
Heckford, Arthur Egerton, Birmingham.
Hood, James Maclay, Glasgow.
Hugon, G. R., Manchester.
Hunter, Sir John, K.B.E., London.
Hurren, Frederick Harold, Coventry.
Ingle, W. L., J.P., Leeds.
Kemp, Henry Thomas, London.
Kreglinger, Albert, London.
Leigh, E. B., Chicago, U.S.A.
Maxwell, Robert W., Frant, Sussex.
Morch, Jacob, London.
Owen, Alfred Ernest, Darlaston, Staffs.
Pearson, John Andrew, Toronto, Canada.
Pierce, Edward Lily, Syracuse, New York, U.S.A.
Pinckard, Mrs. R. A., London.
Richardson, Ralph, Weybridge, Surrey.
Saunders, Samuel Edgar, M.I.N.A., Isle of Wight.
Scott, Thomas Henderson, Assoc.M.Inst.C.E., Trinidad.
Simms, William Archer, Swansea.
Smith, Major S. Heckstall, London.
Tucker, Percy Earle, Yeovil.
Twiggs, Alderman H. W., Bristol.
Waddington, George, London.
Wakefield, Alderman Sir Charles Cheers, Bt., London.
Walker, Henry T., London.
Welch, Henry John, Bromley, Kent.
Wilkinson, Samuel Blaze, Northampton.

The paper read was—

THE MANUFACTURE OF MARGARINE IN THE UNITED KINGDOM.

By Sir William George Watson, Bt.,
Chairman of the Maypole Dairy Company.

When your Secretary invited me to give you a paper on the use and manufacture of margarine in Great Britain, he informed me that a very interesting paper upon the subject of Butterine or Oleo-Margarine butter, was read before your Society by the late Mr. Anton Jurgens in 1884.

On perusing that paper I am struck with its apologetic character. In those days it was apparently considered necessary to apologise for either manufacturing or selling margarine. To-day apologies of this character are unnecessary. Margarine has now won by its own merits an established position in most countries and has, since the war, proved a boon to all classes of the population. This in spite of the admitted fact that since the outbreak of war the quality of the "overkept" or "held up" raw materials has sometimes affected the quality of the product, and will probably reduce the quality still further in the near future.

I cannot agree that the success of margarine is caused through its similarity in appearance to butter, and in proof of this it is only necessary to mention that the greatest consumers of margarine per head of population are the Danes, who many years ago passed laws to forbid manufacturers making margarine which was coloured to resemble butter.

These laws were passed in Denmark to protect the very important Danish butter industry, and were probably at that time also expected partially to kill the growing margarine industry. Instead, they had the curious effect of greatly increasing the home consumption of margarine in Denmark, and of inducing the largest Danish margarine manufacturer, Mr. Otto Monsted, to build works in England in 1888 to enable him to retain his British customers who still wanted to buy coloured margarine.

The establishment of these works, in which my family became partners in 1889, was a principal cause of the increase in the British manufacture of margarine. To-day over 80 per cent. of the margarine made in Great Britain is under the control of men who were trained in the factories established by Mr. Otto Monsted and his partners or successors, The Maypole Margarine Works, Limited. This proves how

bringing new industries into this country disseminates technical knowledge.

Although the margarine industry was first established on a large scale in Holland, Denmark was a very close second in the field. The Dutch makers established factories in Germany and Belgium when those countries put a tariff upon margarine, but they did not take any steps to establish works in Great Britain until the difficulties caused by the present war practically compelled them to do so. After first establishing themselves in Holland and Germany, it paid them best under the conditions to import their raw materials (chiefly from British Colonies) to Germany and Holland and manufacture them there for the British markets.

It has always seemed to me to be unwise for Great Britain to continue dependent upon foreign countries for the manufacture of important foods, especially so for food made from raw materials produced in the British Empire. Maypole has always endeavoured to encourage and extend the British manufacture of margarine, and in recent years the crushing of edible nuts and the refining of the resultant edible fats.

After the outbreak of war, the then Colonial Secretary (Mr. Bonar Law) appointed a committee, upon which I had the pleasure of serving, under the chairmanship of our honoured Chairman of to-day (Sir Arthur Steel-Maitland). This committee was appointed to advise the Government on the steps to be taken to establish crushing and refining mills in the United Kingdom, and to extend the British margarine industry, and so provide a home market for the copra, palm kernels, and other oil nuts and seeds which the British colonies had previously sent to Germany.

This committee made their report, but I fear it did not then have the desired effect, as Maypole's factory could only work at half its capacity in 1916, owing to the handicap and restrictions on the sales at Maypole's branches, which were caused by the monopoly which was then given to sugar retailers and their power to make "conditional sales."

My protests and appeals to the Government to remove the handicap on our output were unsuccessful at that time, and I shall always consider the Government were very badly advised to ignore my protests, and continue to curtail and handicap the British production and sales of margarine during that war year, when the average imports of butter showed a decrease of 1,614 tons per week. It would have been much wiser to have then encouraged Maypole, and asked them further to increase their factory and output.

However, early in the year 1917 the British Government decided to give encouragement to the home manufacture of margarine. They then prohibited and made it an offence to make "conditional sales" with sugar. This prohibition (when enforced) removed the handicap on "Maypole" sales of margarine, and enabled the company to work their factory at its full capacity, and promptly to add over 900 tons to their weekly output and sales; this at a time when extra supplies of margarine were urgently wanted, owing to the increasing shortage of butter and the effects of the submarines and blockade policy on the Dutch supplies. In this year the British Government also prohibited the export of oil seeds to Holland, so the Dutch margarine makers had then to import their raw materials for making margarine in the form of oil. This prohibition considerably lessened the supply of cattle feeding-cakes for the Dutch cattle, and at the same time increased the supply of food for British cattle.

During the first six months of 1916 Holland had sent over 4,000 tons of meat, butter and cheese per week to Germany, and it therefore seemed advisable for our country to discontinue sending to Holland the raw materials for manufacturing cattle feeding-cakes.

The figures given on p. 214 show the large decrease in the imports of butter and the increase in the imports of margarine in 1916, and the large increase of the home manufacture of margarine in 1917, when the restrictions on Maypole sales and output were removed.

In 1913 and 1914 over two-thirds of the home production of margarine was made at Maypole's factories, and they now manufacture over 2,000 tons a week at their Southall factory. This quantity is about equal to the average weekly production of butter in the United Kingdom.

Since the outbreak of war, Maypole and their chemists have been instrumental in assisting two of the largest British companies—Messrs. Lever Brothers, Ltd., and the Wholesale Co-operative Society, Ltd.—to commence the manufacture of margarine in this country: and the two largest Dutch companies have nearly completed margarine works here, so there is every reason to hope that British factories will soon be in a position to render us independent of foreign countries for the whole of our supplies of margarine.

When Mr. Anton Jurgens read his paper in

	1913.	1914.	1915.	1916.	1917.
	Tons.	Tons.	Tons.	Tons.	Tons.
Average weekly quantity of margarine manufactured in Great Britain	1,611	1,728	2,219	2,479	3,564
Average weekly quantity of margarine imports from all countries	1,460	1,470	1,973	2,647	*
Average weekly quantity of margarine imports from Holland	1,427	1,445	1,947	2,633	*
Average weekly quantity of butter imports from all countries	3,980	3,831	3,706	2,092	*

Average weekly quantity of butter imports from Holland	147	177	43	35	*

* Not published.

1884, margarine was manufactured almost exclusively from animal fats and liquid oils. To-day, coconut oil and palm-kernel oil have nearly displaced the animal fats.

In the discussion which followed the reading of Mr. Jurgens' paper, Mr. Otto Hehner said that coconut oil was the only vegetable fat which at all resembled butter. At that time the manufacture and preparation of vegetable fats for other purposes than soap-making were only in their very first stages.

However, gradually new methods of treating the vegetable fats were introduced, and in the early nineties coconut fats had already gained a certain place in the market as a cooking fat. During the following ten years, as refining methods were perfected, it slowly but surely found its way into the manufacture of margarine.

Other fats, such as palm-kernel oil, were also introduced, with the result that about 90 per cent. of the margarine manufactured is now made exclusively from vegetable fats and oils; and in my opinion the quality, when scientifically manufactured, is superior to that made with animal fats. Before the war the prices of vegetable fats were often equal to the prices of animal fats, but since the war the greater scarcity of animal fats has made the latter more expensive than the vegetable fats.

Many and various difficulties have had to be overcome before the vegetable fats could be refined to the degree of perfection required to enable them to be utilised in the manufacture of margarine.

Not only has it been necessary to design, improve, and again improve, upon the milling machinery used for the crushing of the nuts, but numerous processes, both physical and chemical, have had to be devised to free the crude oil from all colour matters, from the contents of free, fatty acids, and from odour—the last being due to the presence of small quantities of volatile substances.

Of these processes should be mentioned:—

1. The washing of the fats with hot water, so as to remove albuminous matters.
2. The filtration and bleaching with various hydro-silicates.
3. Neutralisation with caustic alkali.
4. Treatment in specially designed vessels, with superheated steam, to remove the volatile substances.

Every process has to be carried out with the most minute care and attention, and in continuous co-operation with the chemical laboratory, in order to ensure a finished product practically without taste, smell, or colour, as the margarine makers of to-day are most particular in the choice of edible fats.

Before leaving the subject of oil refining, I would mention the very great developments in this industry due to the war; for instance, Maypole's refining works at Erith have practically trebled their output.

I will now turn to the margarine-making proper, and continue with a description of the manufacture and processes as it progresses.

The solid vegetable fats are, as a rule, hard and brittle, and the first step is to melt and mix them with the amount of liquid oil necessary to soften them to such an extent that they can be easily spread on bread.

The mixture of fats and oils is practically

colourless, and as a yellow colour is desirable a small amount of butter colour is added.

The next step is the churning process, wherein the fats are churned with ripened skim milk in such a way that a very intimate emulsion of milk and fat is formed.

This churning process has undergone considerable developments, and I am pleased to say that our works have been among the pioneers in this direction. Five or ten years ago the process was carried out in large vessels of several tons capacity, provided with a steam-driven stirring device. The whole arrangement was very bulky and expensive, and necessitated constant attention and considerable loss of time.

The new plant consists of a motor-driven emulsifier, in which the emulsification is carried out continuously. This arrangement requires very little attention, and only a fraction of the power needed for the old plant. The new emulsifying plant has been in use in our works for several years, and has also been adopted in several other factories with which we work together in technical matters.

The liquid emulsion produced in the emulsifiers is spread on the surface of rotating cooling drums, and thereon cooled to such an extent that it immediately sets and is scraped off the drums as finely crystallised flakes.

The very fine and uniform crystallisation of the fats essential for the making of vegetable margarine has only become practical by the introduction of the above-mentioned cooling device, and by the guide of microphotographic reproduction of the crystallisation formed thereon.

In this direction also I am pleased to say that our works have been doing pioneer work, and the first successful drum-cooling was carried out in Southall as early as 1906. Before the introduction of the surface-cooling of margarine emulsion, the cooling was generally done by spraying the emulsion into icy-cold water.

At this stage of the manufacture the salt is added, and the margarine is worked on butter rollers and butter blenders until it has a consistency which resembles butter.

The milk and its treatment is of the greatest importance in the manufacture of margarine. It has been found necessary to procure the best and freshest milk obtainable, and to make such arrangements that it is received in our dairy within six to eight hours from milking time.

In the dairy the milk is separated (the cream being used for butter-making), and the skim milk is pasteurised and cooled practically to freezing-point and then run into tanks, where it is stored under cold store conditions.

The souring or ripening of the milk is generally accepted as the most essential process, and it is hardly necessary to state that for this purpose only pure cultures of lactic acid organisms are used.

The souring process itself is carried out in propagators, in which the process goes on continually. The sweet milk is run in at the top of the propagator as the equivalent amount of fully ripened milk leaves the plant. In this direction also our works have broken away from the old process of souring, when the milk was left to ripen in large open vats.

All these processes are governed by the strictest rules of hygiene and sanitation. Margarine, like butter, being a most delicate substance, and one which is very easily influenced by organisms such as bacteria and moulds, calls for the most careful treatment; further, as the milk offers the most ready ground for the development of such organisms, you will readily understand that the hygienic conditions in a margarine factory cannot be too highly rated. In fact, nothing less than the actual sterilisation of the utensils and raw materials will suffice, and there is a constant hunt for germs in every corner and every pipe. Live steam has proved to be the most effective, and in every respect the least harmful, method to adopt for sterilisation in a food factory.

In our margarine works at Southall we have gone so far in this direction as to instal expensive plant for purification of the air in the work-rooms. The plant is so constructed that the fresh air is drawn from shafts protruding high above the buildings, and is passed through a chamber where conditions of constant rain prevail. The water is distributed over the whole area of this chamber by means of hundreds of sprays which eject the water as a very fine rain. The passing of the air through this water frees it from dust and organisms and makes it clean and humid, like the atmosphere after heavy summer rain. Further, the plant contains heating and cooling elements which enable the air to be cooled in the summer and heated in the winter. By means of a system of air-ducts the treated air is distributed through the work-rooms. The result of this installation has been most satisfactory, and an atmosphere of constant humidity and temperature can be practically maintained throughout the year. It

has not only largely assisted us in raising the keeping quality of the margarine, but, although no statistics are available, we are of the opinion that it has raised the standard of health of the workers generally.

The raw materials for the margarine industries —*i.e.* copra, palm kernel and groundnuts—come chiefly from the British Empire, and in view of the prospective great shortage of butter and animal fats, caused by the depletion of European cattle stocks during the war, the future of British margarine manufacturers is assured, provided that they will turn out a satisfactory quality. To do this they must secure the best plant and raw materials and treat them under the expert guidance of the best chemists and scientific experts.

There is a great future before the products of British tropical Colonies, and we can look to them greatly to augment our food supplies and so help to counterbalance the shortage of animal fats.

Prior to the war most of the smaller British margarine manufacturers found it very difficult to compete successfully with the much larger Continental manufacturers.

It is naturally difficult or impossible successfully to establish an infant industry in Great Britain in opposition to old-established large and powerful Continental interests, who are determined to hold the trade and whose home market is fully or partly protected by tariffs. Maypole was able to do this only because they had very strong financial resources, and they owned their own retail distributing stores.

Although, thanks to the effects of the war, the British margarine manufacturers are now unlikely to require any protection, yet I suggest that our politicians should mutually agree to encourage the manufacture in the United Kingdom of foods and essential and important articles like aniline dyes, leather, etc., even when that encouragement may in some few cases necessitate temporary protection or a development grant for a few years, until the infant industry is firmly established, and sufficiently strong and experienced to bear the competition, fair and unfair, which powerful and protected Continental trusts can bring to bear on any British infant industries.

Once an industry is firmly established, the favourable conditions for manufacturing in the United Kingdom should render it independent of any permanent protection tariffs or development grants.

At Maypole's refining mills and margarine works we consider the laboratories to be one of the most important parts of the organisation, and no expense for research is spared there which will help towards future progress. I fear that in the past some British manufacturers have not attached so much importance to the expert and scientific assistance of their chemists and chemical engineers as their Continental competitors.

My experience in business convinces me that the industrial victories of the future will be won by those nations who encourage their home manufactures and scientific education, and whose manufacturers make the greatest use of chemical and scientific knowledge.

It will also be advisable to link closely together the interests of employers and employees by means of profit-sharing and co-partnership. The manufacturers who continue to rely on obsolete and old-fashioned "rule-of-thumb" methods, and neglect to secure efficiency and the interest and goodwill of their employees, are doomed to failure.

It is to be hoped that our public schools and universities will in the future give greater attention to the teaching of natural science and chemistry, even if this necessitates less attention to the teaching of Latin and Greek.

I should like to suggest the endowment of scholarships by manufacturers and others to enable the brightest scholars at our schools further to pursue their studies in this important subject.

I have dealt very fully with the manufacture of margarine, and before concluding my paper I should like to say a few words upon its distribution and the queues which have recently arisen during distribution, and for which Maypole have been thoughtlessly blamed.

Prior to the war about 75 per cent. of the margarine was distributed by the multiple shop companies, and sold by them at low prices very largely to the wage-earners in industrial centres. When butter became very scarce and dear everybody rushed to the multiple shop companies to buy margarine.

The demand soon exceeded the supply, and retailers, some of whom had not previously dealt in margarine, struggled to get supplies. The multiple shop companies endeavoured, by selling only a certain portion of the week's arrival each day, to reserve some for their old working-class customers who have to shop at the end of the week. Maypole was greatly blamed by the Islington and other food control committees for adopting this course,

but immediately they stopped it they were requested or ordered to reintroduce it by many other local food committees.

The growing shortage, combined with the practice of reserving supplies for the working-class customers, caused queues, and it was believed by some that the queue evil would be cured and the poor get their supplies by increasing the number of distributors.

The only real cure for queues was either to increase the supplies or compulsorily to lessen the demand, and secure equal share for everybody by the adoption of an individual rationing scheme. One of these courses is necessary whenever an essential food is in short supply, and a maximum price is therefore imposed and conditional sales are forbidden.

The fact that conditional sales were allowed with sugar in 1916 misled our politicians, and apparently made them think that individual rationing of an article in short supply was not necessary, and that they could safely "wait and see."

When the Food Ministry did commence to ration, they, in the first place, rationed the wholesaler and the retailer instead of the consumer.

Some local food committees have now commenced to ration the consumer, but it is probable that difficulties will arise if they continue to bind each consumer to a particular retailer, as this will increase cost to consumers, sacrifice freedom, and involve immense detail labour and responsibility on officials for the stocks and supplies to each individual retailer. It may be practicable to bind a consumer to a particular retailer for dry goods, but I fear it will be very difficult with perishable articles like margarine and meat.

In my opinion rationed goods should be obtainable on presentation of a card with detachable coupon at any retailer in the food area, who should be bound to sell if he has them in stock. This would be practicable, and queues would also be prevented if the total demand in each district was, by the use of these cards and detachable coupons, compulsorily kept below the known total supply.

It may soon be found necessary to introduce a national individual scheme of rationing, as it is improbable that the Ministry of Food can continue to control or co-ordinate the many different schemes put in operation by the local food committees.

Some of these local food committees recognised what they owed to Maypole for their supplies of margarine, and gave them consideration; but others made things very difficult. For example:—

Halifax, Sowerby Bridge, and many other local food committees, ordered Maypole to cease retailing margarine, and only allowed sugar retailers to sell margarine. Maypole were not allowed to sell sugar, so they were put out of the retail margarine business in many towns.

Wellingboro' local food committee ordered Maypole to advance their retail price from 11*d.* to 1*s.* per lb., and to cease selling to all their old customers and only serve members of the co-operative society whose names commenced with A, B, or C.

In some towns the local food committees ordered Maypole to advance their prices for margarine to consumers, and then transferred part of Maypole margarine to a co-operative society who give dividends on purchases, and so made their net price below the obligatory price at which Maypole were made to sell it.

Many retailers to whom Maypole margarine was transferred had never previously sold margarine, others made a condition and refused to supply margarine to those who were not registered with them for sugar or a member of their co-operative society.

Maypole shops were open to all, including those to whom sugar retailers would not or could not supply margarine. Maypole had no right to make a condition or to refuse to supply anybody, so they were powerless to prevent queues in the absence of an individual rationing scheme.

Meat is now in short supply, so the cash butchers who sell cheaply and supply the working-classes will be the innocent cause of queues until the introduction of an individual rationing scheme to secure an equal share to everybody.

It is a pity that the authorities failed promptly to recognise that the queues are a symptom rather than a disease, and it is therefore more necessary to remove the cause than to disperse the effect.

It would have been in the interests of the poorer consumers if a national individual rationing scheme had been prepared in good time, and adopted immediately supplies were short; the distributing business could then have remained in the hands of those who have proved their ability to distribute efficiently and economically.

Until quite recently Maypole distributed

their make of margarine at 11*d.* per pound, but under the new conditions prices must be higher, and there will be waste and losses in hot weather, owing to the low melting-point of nut margarine. Nut margarine, like fish, is unsuitable for distribution at many small shops during hot weather.

If some members of the public still mistakenly believe that Maypole is blameworthy and responsible for the short supply of margarine and the consequent queues, I hope that those who are present to-day will form a different opinion.

Maypole can only plead guilty to two things:—

Spending over £500,000 upon buildings and machinery (double pre-war prices) to enable them to increase the production of British margarine.

Distributing margarine to consumers at low prices and free from all conditions. They sold cheaply by the express wish of the Government. They only advanced their retail price when requested or ordered to do so by many local food committees.

Maypole is not deserving of either criticism or punishment, and they therefore severely felt the injustice of being made the scapegoats for the effects of the margarine shortage.

In conclusion, I should like to thank you for the patience with which you have listened to me and at the same time I crave your indulgence for troubling you with this defence of the good name of my company. It is still permissible to defend one's honour and good name, although all private financial interests must now be made subservient to the national interests.

I hope that my paper will help to prove the necessity of encouraging the study of science and chemistry, and the advisability of giving support to the home production of margarine and other important foods, and so render them less vulnerable to the submarines of our enemies.

DISCUSSION.

The Chairman (Sir Arthur D. Steel-Maitland, Bt., M.P.), in opening the discussion, said that in so far as the paper was a defence of the good name of the Maypole Company, he was sure that no such defence was really needed, for it was well known that that company, and all other makers of margarine, had done their best to produce margarine to their utmost capacity as supplies and prevailing conditions permitted. The problems in connection with the manufacture of margarine formed an epitome of all the various kinds of problems with which Great Britain was faced at the present moment, and would be faced after the war. For instance, at the outbreak of the war this country was placed in a position, which was absolutely unnecessary, of dependence on foreign supplies for some essential articles, and she was in that state of dependence in a great measure with regard to margarine. There was really no reason on any economic grounds why this country should not have produced margarine just as much as those countries which were our chief suppliers; but different firms in the same line of business, or in connected businesses, did not stand together in this country as they did on the Continent. The reason why margarine manufacture became established to a large extent on the Continent was because there was a distinct organic interconnection there between the firms that carried out the various processes of refining and marketing, etc. That again was an instance of another problem which would face this country after the war; and he desired to emphasise the fact that if this country wished to be in a position to face competition in the future, its people would have to realise that under modern conditions industries had got to work in organic relation with one another, instead of as a number of separate, and very often warring, independent units. When one began to go into the question of oils and fats, of which the subject of margarine formed part, one saw how complicated the industry was. There were eight or ten principal oils and fats imported into this country—linseed, cotton seed, soya beans, coconut oil, palm-kernel oil, tallow, whale oil, stearin, etc.—and when one came to deal with the question of providing them methodically, instead of allowing them to come in according to supply and demand, it was found that while two or more than two might be interchangeable for any one purpose, those which were interchangeable for one purpose were not interchangeable for another purpose. For instance, most of them could be used for making soap, but only some could be used for edible purposes. Before margarine could be made, the raw material had to come to this country in the form, say, of palm kernels, which had to be crushed to obtain the oil from them. Then that oil had to be refined, and after that machinery was required for making it into margarine. At any moment at any one of those stages there might be a hitch in the course of manufacture. For instance, we had not been accustomed in this country to use palm kernels to any great extent before the war, and they required a different kind of machinery to crush them economically from that required for crushing other oil seeds, the result being that we were held up for some time because we had not got that particular kind of crushing machinery. Then again, with regard to refining, at first only certain kinds of oils and fats were thought fit for human food, but by degrees new processes of refining and hardening oils made certain types of oils fit to eat which were not thought suitable before. He had

personally tasted refined and hardened whale oil, which had been coming into use on the Continent for making margarine, although it had not yet been used in this country, and he did not think it was so good as other oils, he could quite believe that it would become so in course of time. The subject of margarine not only was an instance of the quite unnecessary reliance placed by this country on foreign supplies before the war, but it also illustrated the problem with regard to raw materials with which we should be faced at the end of the war. There were, of course, many controversial questions connected with the adequate supply of raw materials after the war, and the subject of oils and fats was one of the most interesting of them, both as regards the supply for our own country and the degree of dependence of Germany on other countries for her supply. In a little book he had just published, called "The Staple Trades of the Empire," he had given a chart showing the main sources of oil throughout the world. It was interesting to note the vast proportion of oils that was produced within the British Empire and the United States. There was a large amount of linseed oil produced in the Argentine, and a great deal of coconut oil produced in the Dutch East Indies, but the greatest production of cotton-seed oil was in the United States; and our African Colonies, India, and, to a certain extent, Ceylon and our Pacific Colonies, produced a very large amount of palm-kernel oil, palm oil, groundnut oil, rape-seed oil, millet, and cotton-seed oil. The German dependence on imported oils before the war was very considerable. He had just made a rough calculation, and found that Germany imported in the year 1913 oil seeds and nuts containing an oil content of just under 600,000 tons, whereas the importations into this country were certainly not two-thirds of that amount, the oil content of the seeds and nuts imported being probably about 380,000 tons. It had to be remembered, however, that, although Germany was dependent to a large extent on foreign supplies, there was a considerable amount of oil seeds and nuts produced in parts of the world outside the Allied control. With regard to the subject of raw materials, the main points to be considered were who had the control in the country of production; would the total supply in the country of production be equal to, or greater than, or less than, the probable demand of the world as a whole; were there substitutes which could be used by Germany in place of articles grown in Allied countries, if those were denied to her; and, lastly, what would be the carrying position at the end of the war, and to what degree was it likely to suffice for the goods that were to be carried. He thought the question of oils and fats was a most interesting illustration of the whole of the problems that would confront this country after the war.

Mr. D. F. Shillington desired to thank the author for his very interesting and illuminating paper, and also to thank the Chairman for his remarks upon edible oils. As to the question of queues, which had been referred to, he would like to suggest that if the author would arrange that at the many branches of his company every person should be supplied with the same quantity of margarine, and that it should be sent from the factory done up in parcels of, say, 1 lb. each, and that every customer should come to the shop with the exact amount of money he had to pay, then there need be no queues. A great deal of time was at present taken up in weighing the margarine, making it up into parcels, and giving change to the customers.

Mr. J. H. Coste said that, with regard to the author's remarks as to the equal value of animal and vegetable fats, Dr. Halliburton had shown, in a paper published in the *Journal of Physiology*, that for the growing animal vegetable fats were not equivalent in value to animal fats, because they were deficient in growth-producing substances. Of course, under normal conditions the human child did not depend on margarine alone for its supplies of fat; but as some such conditions might come about, he thought the question he had mentioned was worthy of consideration.

Mr. J. E. Trigge (Niger Company) said he did not think cheap margarine was an unmixed advantage at the present juncture. During the last few months, before the position became acute and the shortage of margarine very pronounced, in many places there was a larger consumption of margarine, butter, and other fats than in ordinary times, which had helped to bring about the present shortage. When margarine could be obtained cheaply the consumption was increased, and supplies had to be brought from abroad to meet the demand. Germany was not altogether to blame for our present shortage of supplies of fat because before the war we had neglected the matter, and were now suffering for our neglect. Twenty-five years ago the speaker's company introduced a new fat into this country for edible purposes, but no one would use it, and consequently he was instructed to take it abroad and introduce it there.

Mr. S. Barnett thought that one good feature of the author's company was its system of profit-sharing. In any up-to-date manufacture in the future some system of profit-sharing would have to be employed if that co-operation between capital and labour which everyone hoped to see after the war was to be achieved. Before he became a manufacturer he had been for fifteen years engaged in the distribution of all kinds of food on a somewhat large scale, and he had no hesitation in saying that this country was now paying the penalty of her policy of neglect in the past. He thought this country was greatly indebted to

anyone who increased the home production and manufacture of food. From his experience as a food distributor, he knew the difficulties which had confronted the author's company and others that had shown enterprise, and the very scanty encouragement they had received from the traders and from the general public in this country. He did not think the Maypole Company would have found a market for the quantity of goods they were manufacturing if they had not had their own distributing shops, and had not begun to manufacture after they had possession of the channels for distributing. One great advantage which this country had derived from the enterprise of the Maypole Company was that the manufacture of 2,000 tons per week of margarine involved the production of an immense quantity of other materials, such, for example, as material which was made into feeding-stuffs for cattle. Margarine manufacturers not only produced margarine but also provided material at a reasonable price which would otherwise have to be imported, and in producing margarine they also helped to produce beef.

Mr. C. Revis said that the author had referred to the necessity of manufacturers employing scientific assistance, and that was a matter which had been greatly neglected by manufacturers in this country in the past. British chemists believed that lessons taught by the war were going to be of great assistance to them. They had responded well to the demands which the present necessities of the country were making upon them, and it was certain that if British manufacturers were going to hold their own in the future they must turn to the scientific men for assistance, as other countries had done.

Sir William George Watson, in reply, agreed with the remarks made by Mr. Revis with reference to manufacturers employing chemists, and said that those chemists should be given seats on the board of directors, as was the case in the Maypole Company, so that they could become fully acquainted with all the details of the business. With regard to Mr. Shillington's suggestions for the abolition of queues, the Maypole Company had already tried the plan of distributing margarine to their City shops in one pound and half-pound parcels, and there the queues had, strangely enough, been worse than anywhere else. As a matter of fact, when a business was doing a cash trade and did not know its customers, and when the demand was in excess of the supply, there were bound to be queues. Many people seemed to think that manufacturers should not be also distributors, but people who were both large manufacturers and large distributors could supply their products at a low cost to the consumer; and British goods, when sold in competition with foreign ones, would only be bought if their quality and price compared favourably with the foreign products. With regard to margarine made from vegetable fats being deficient in growth-producing substances, his company had taken the necessary steps to have the matter investigated.

The Chairman, in proposing a hearty vote of thanks to the author for his interesting paper, said that, with reference to Mr. Trigge's suggestion, he did not think that the shortage of margarine was due to any great extent to the increased consumption in this country, although there had for various reasons been a bigger demand during the war. If anything, our supplies were less now than they previously were. The home production of margarine had, of course, enormously increased, and was now three times as large as it was before the war. But what had to be compared were the home supplies of margarine, the home production of butter, the importations of margarine, and the importations of butter; and it was the importations of butter, which had fallen off so very largely, and the fluctuation in the supplies of foreign margarine, which had diminished our total supply of fats. What this country had gained in the home production of margarine it had lost very largely in decreased importations, and it was probable also that the home production of butter had fallen a very great deal. As regards the employment of scientists by manufacturers, he though the use of science in commerce would have to be much greater after the war than it had been before. Manufacturers should not only go to a chemist to obtain his advice on certain points, but they should employ chemists permanently, and let them have an influence on the whole conduct and management of the works.

The vote of thanks was carried, and the meeting terminated.

AMERICAN POTASH.

The production of potash in the United States was greatly increased in 1916, according to a report of the United States Geological Survey. The total production of potash salts and potash products in the United States in 1916 represented about 10,000 short tons of pure potash, with a net value at point of shipment of at least $3,500,000. This is ten times the value of the production reported for 1915, but the figures submitted by many of the producers represent only a start made towards the end of 1916.

The potash produced in 1916 was derived from the following sources:—

Mineral sources.—Natural salts or brines, 3,850 short tons; alunite and silicate rocks (including furnace dust recoveries), 1,900 short tons.

Organic sources.—Kelp, 1,100 short tons; pearl-ash (mostly from hardwood ash), 220 short tons; miscellaneous industrial wastes, 1,750 short tons.

The largest output comes from the Nebraska alkali lakes, but the natural saline deposits else-

where are beginning to make important contributions. The production of potash from organic sources is about half that from mineral sources. The recovery of potash from pearlash is an old-established industry.

PRODUCTION OF BEESWAX IN BRITISH EAST AFRICA.

The gathering of beeswax in the East Africa Protectorate is almost entirely in the hands of the natives, who obtain the product from wild hives in the country. Very little scientific apiculture is practised, and that only by the European settlers in the highlands. Notwithstanding the present small production of honey and beeswax, writes the United States Consul at Mombasa, the higher altitudes of the Colony are peculiarly well adapted to apiculture. Clover is an abundant crop, and other flowers are plentiful. There are two rainy seasons, no winters, and so far no serious bee diseases have developed. The Government is giving every encouragement to the industry, and the active interest of the settlers is being aroused to the opportunity. It is believed that the near future will witness a substantial development in this industry.

During the fiscal year ended March 31st, 1915, the total export of beeswax amounted to 1,563 cwt., valued at £10,000, of which Germany took 50 per cent., France 15 per cent., the United Kingdom 14 per cent., Belgium 11 per cent., the remainder going to Italy and Holland. For export, the product is packed in bags containing 5 frasilas (180 lb.). There is no export duty. The import duty on beekeeping supplies is 10 per cent. *ad valorem*, the value for customs purposes being based on the c.i.f. Mombasa cost (amount of invoice plus freight and shipping charges). There are no statistics available as to the amount of importation of these supplies.

CHEMICAL INDUSTRY AND PATENT LAW.

A paper on the above subject was recently read before the Society of Chemical Industry by Dr. F. W. Hay, of British Dyes Limited. The author expressed himself on the following lines:—

In view of tho fact that the prosperity of the country depends so largely on industrial activity, and that no industry can maintain its reputation in the markets of the world without constant improvement, the question whether the inventive talent of the people is stimulated and assisted in every respect is a matter of primary importance. We have a fairly highly developed patent system in this country, which is, in fact, the oldest of its kind. In its fundamental conceptions it has been incorporated in the Statute Law of almost all other countries. Its governing principle dates back to the Statute of Monopolies of 1623, and is still on a sound basis, but it has never been made to produce its full beneficial effect.

According to this governing principle of our Patent Law, a patent, in order to be valid, should cover a new invention. The Patent Office, however, owing to the inadequate system of preliminary examination allotted to it by the Act of 1902, merely examines whether the invention to be covered by a patent is new with regard to prior British patents of the last fifty years. These British patents only represent a fraction of the industrial development that has taken place, as so many discoveries are made in other countries. Owing to this very incomplete system of examination, patents issued in this country cannot be considered to contain any reliable evidence of novelty. Those that are granted for genuine inventions are inundated by a large proportion of patents delivered for inventions that are new only as far as prior British patents are concerned, but are not in fact entirely new. The law, however, stipulates, and rightly so, that the invention should be new in every respect: hence a serious anomaly exists between the attitude of the Courts, which consider all prior publications, and that of the Patent Office, which examines prior British patents only. A patent sealed by the Patent Office is therefore liable to be upset in Court on the grounds of anticipation as soon as it is issued. The inventor finds it exceedingly difficult to introduce his invention owing to the lack of consideration given to patents in this country, and the manufacturer is deterred from using a new invention, because the patent he is offered may or may not be a valid instrument of defence against infringers.

It does not seem expedient to leave the novelty of the invention to be determined by the Courts. The novelty of all inventions to be protected by patents should be investigated by the Patent Office by means of a *general system of examination*, covering all prior British and foreign publications. Without demanding any particular standard of novelty, or applying the criterion of a "new practical effect" adopted in Germany, patents should be granted only for inventions that contain some novel feature over and above the inventions disclosed in the prior publications. All other applications for patents should be refused.

Specifications relating to chemical industry, and describing an invention which seems problematical or obscured by irrelevant or misleading statements, might in certain cases be verified in suitable Government laboratories, so as to avoid the delivery of patents that are intended to obstruct. The supply of samples is deemed insufficient for this purpose. As an alternative, the system of granting patents recently adopted in Switzerland might be found

an effective measure against the delivery of obstructive patents.

The public should be allowed five years within which the patent could be revoked on the grounds of anticipation, inadequate description or prior use, and the validity of the patent should then no longer be open to attack in Court, so as to give greater security to any new manufacture depending on patent rights.

The Courts find great difficulty in dealing with litigation relating to chemical industry, and frequently fall into serious scientific error. The judge has to rely on expert evidence which he is unable to understand, because years of scientific training are required to be able to cope with the highly technical evidence brought forward. No demonstration *ad oculos* can, as a rule, be made. Great uncertainty, therefore, prevails with regard to patent litigation relating to chemical manufacture, and even wealthy companies often prefer to put up with a certain amount of infringement rather than defend their rights. It is therefore proposed that all actions in Court connected with infringement of patent rights, should be tried in the presence of a "Technical Jury," consisting of experts engaged in the industry or science to which the action relates and assembled in the manner of a "Special Jury."

FORESTRY WORK IN NEW ZEALAND.

The principal Government forestry nursery and reserve of New Zealand is at Rotorua. Mr. H. A. Goudie, General Superintendent for the North Island, has given the United States Consul-General at Auckland an opportunity to study the nursery and plantation, where the first forestry work was begun in 1898. Since that date, writes the Consul-General, 58,459,000 forest trees had been propagated in this nursery up to March 31st, 1916, out of a total of 104,835,900 for the entire Dominion since the beginning of the industry; and more than 14,700 acres of trees had been planted on the two adjoining reserves, out of a total of 27,228 acres for the Dominion.

The soil for the nursery is thoroughly prepared by being cultivated and fertilised until it becomes a rich, black sandy loam before planting is begun. It is then laid out in beds about 8 ft. wide, and 100 ft. long, into which seeds for about 200,000 plants each are sown. A very great majority of the plants are cultivated until they are two years old, when they are transferred to the plantations, or sold to individual growers at the cost of production. The output of the nursery for the past few years has varied from 2,600,000 to 6,000,000 plants.

Only eight Government forest plantations of any importance are maintained in New Zealand. The largest two are just south of Rotorua, and cover more than 21,000 acres. About two-thirds of this area has been planted with trees averaging 32 square feet to the tree. The work is thoroughly done, and it is calculated that at the end of thirty years some good saw logs may profitably be cut from the eucalypts and the more rapidly growing pine forests. Meanwhile, many trees which are cut to thin out the timber may be used for poles, posts, sleepers, etc., while a considerable quantity of firewood is sold annually from the plantations. The total cost of the plantations to March 31st, 1916, had been £224,000.

Tests have been made with many different species and classes, with a view to determining what timber can be most advantageously grown in New Zealand, with the following selections:—

General building construction (scantling, weatherboards, etc.): Corsican pine, heavy pine, Weymouth pine, Monterey pine, Douglas fir and eucalypts.

Joinery (doors, windows, etc.): Weymouth pine and Douglas fir.

Flooring, lining, and interior finish: Any of the kinds in the two preceding groups.

Bridge-building and similar heavy construction: Eucalpyts, Douglas fir, and Corsican pine.

Coach-building: Eucalypts for framing, Corsican pine, heavy pine, Weymouth pine and Douglas fir for boards and panels.

Railway ties, telegraph poles, and fencing: Eucalypts.

Packing cases, kegs, and butter boxes: Any of the pines mentioned in preceding groups, and, in addition, sweet chestnut and poplar.

Boat-building: Eucalypts, Douglas fir, Corsican and heavy pines and larch.

Turnery: Eucalypts, ash, oak, chestnut, poplar, and pines.

Furniture: Eucalypts, sweet chestnut, Weymouth pine, Douglas fir, poplar, ash and oak.

The best results are obtained from American pines and the Australian eucalypts. Many European larch trees were planted several years ago, but with unsatisfactory results. During the year ended March 31st, 1916, much less work than usual was done in Government forestry. In 1916–17, however, there were 5,848,930 forest trees raised at the four State nurseries in New Zealand, and 5,419,569 trees were planted in the eight Government plantations, covering 2,764 acres. The total area planted since the start of operations in 1896 thus amounts to 29,992 acres. Enough seeds have been ordered from France and America for sowing next spring to produce 2,500,000 trees, to be used at the Rotorua nursery alone.

It is estimated that at the end of thirty years the native forests of New Zealand will have been exhausted. The annual consumption of lumber will then require the cut from at least 20,000 acres of timber lands, which means that about that area must be planted annually if the supply is to be provided by the Dominion.

In this the general public is beginning to realise that it can materially help by planting small patches on farms and along partition fences, and the Government proposes to supply the young trees at cost.

ENGINEERING NOTES.

Caproni Flying Machines.—At a recent interview with Reuter's correspondent, the brothers Caproni, the celebrated designers and builders of Caproni aircraft, says *Chambers's Journal*, expressed a belief that, after the war, lines of aircraft will run between various towns and countries, the machines being luxuriously fitted with accommodation for one hundred or more passengers, where the speed will range up to one hundred and ninety miles an hour. They advocate aeroplanes with two or three motors of 300 to 500 h.p. each, as the adoption of several engines forms a guarantee of safety. These authorities also predict the construction of aeroplanes for service between Europe and America, having accommodation for fifty or sixty passengers, immediately after the war, and they point out that Caproni triplanes are also capable of carrying thirty passengers between Milan and Turin. The foregoing predictions are supported by the statement, on good authority, in *Aviation*, that an aeroplane is being built in Italy with motors of 3,000 h.p. which is designed to carry fifty passengers.

Trinitro-toluol as Substitute for Dynamite.—Many by-product coke plants in America are already engaged in recovering quantities of trinitrotoluol for manufacturing munitions, and many plants which will recover this explosive are being erected. Its superiority to picric acid was plainly demonstrated early in the war. It is now a question, according to Mr. M. A. Allen, writing in the *Mining and Scientific Press*, U.S.A., of November 10th, whether the trinitro-toluol which is recovered by these plants cannot be put on the market in competition with dynamite as a commercial explosive after the war. On the face of the matter, trinitro-toluol is a much more desirable commercial explosive than nitro-glycerine. It does not freeze, does not melt until a temperature of 81° C. is reached, does not ignite until a temperature of 300° C. is reached, and even then does not explode, does not give off the slightly volatile gases which produce severe headache when dynamite is handled, and does not deteriorate under water. The only serious objection to its use is that the explosion produces a large volume of carbon-monoxide gas. However, this is also the case with nitro-glycerine, and dynamites used for tunnel driving are mixed with nitrate as an oxidizer to prevent the formation of this gas. The same thing could, of course, be done with trinitrotoluol. Apparently the chief thing remaining to be worked out is the process of putting the explosive up in convenient form for handling, as is done with nitro-glycerine in dynamite sticks.

Titanium.—It is just announced that there has been a big discovery of titanium in Korea, where the Governor-General has been engaged for some time in the investigation of the mineral resources of the peninsula and the collection of samples of tungsten ore produced in the colony. While examining the various samples of tungsten ore, says the *Indian and Eastern Engineer*, experts discovered a vein of this rare mineral. The newly discovered titanium mine is located in a mountain district of Kanguon-To, not very far distant from Seoul. It has quite rich veins, and, in the opinion of experts, can furnish ample supplies of the rare mineral for industrial purposes. A number of uses have been discovered in the United States for this mineral. By mixing with steel, the hardness of the metal is wonderfully increased. A slight addition of carbon may increase the elasticity of the compound. Thus manufacturers of rails, cutlery, springs, and other articles, have found it an indispensable material for them. In Japan the mineral has been discovered in several places, but it has formed no large deposits available for industrial purposes. It is said that the present discovery in Korea will prove a great help for industrial workers, enabling them to produce certain kinds of steel materials now imported from America.

Arch Dam of Sharp Radius in New Mexico.—One of the shortest radius arch dams for its height yet built is nearing completion on the Cimarron River, New Mexico. The Eagle's Nest dam is 140 ft. high, 30 ft. of which is below the river bed, and has a radius of 155 ft. It is 8 ft. wide at the top and 46 ft. at the base. It drains the Moreno Valley, in Colfax County, at a point where a red granite and porphyry dike, forming a prehistoric lake, has been cut through. The cañon is therefore narrow—40 ft. at the base of the dam and 300 ft. at the crest. The project is to impound 80,000 acre-ft. in the remade lake, to irrigate 30,000 acres. As the dam is 6,000 ft. above sea-level, the season is short, and construction must be carried on from April to October inclusive. Concrete is prepared in a central plant located at the down-stream toe, below a crushing and screening outfit. The spillway at the north end is in a granite saddle of the rock. It will have a length of 50 ft. and a depth below crest of 7 ft., giving, with 1 ft. freeboard, a capacity of 350 sec.-ft., which is in excess of the maximum flood recorded. The outlet tunnel through the rock at the south end has four inlets, at different elevations, leading into the gate-control shaft. The above particulars are abstracted from the *Engineering News Record*.

London Tube Railways.—It is, perhaps, not generally known that the late Sir John Wolfe-Barry was a vigorous opponent of the tubes, with their cost and annual lift and ventilating working expenses, and their absence of the facilities for access to platforms and for through traffic to or from the

suburbs. The tubes constructed since, owing, no doubt, to the same disadvantages, have been condemned in New York, Paris, Buenos Aires, Sydney, and other cities. The objection, *per contra*, that the sewers, water and gas pipes, etc., would be interfered with, has been successfully surmounted by Sir John himself, who was engaged in the construction of the Metropolitan and Metropolitan District Railways, and ought, presumably, to know.

Canal Motor Boat.—Recently an interesting trial trip was carried out on the Birmingham Canal with a monkey-barge which had been converted to power by the fitting of a detachable paraffin motor. The motor employed was a four-cylinder Sterling engine, developing 17 brake-h.p. at 600 revolutions per minute, and geared down 25 per cent. to increase the propeller efficiency. It was mounted aft on the raised cabin-top, and the power is transmitted to the vertical shaft, which takes the line of the sternpost, through two shafts, one of which is hollow and arranged to telescope into the other. These telescopic shafts are necessary, in order to allow for the varying distances between the engine and the vertical propeller shaft when the propeller attachment is put hard over to port or starboard for steering. There is a universal joint fitted, of course, at each end of the transmission shaft. This does away with any need for engine alignment, which is a necessary point in a portable equipment that is intended for service on different boats. As is customary in most outboard sets, the propeller swings round with the rudders, which has the effect of making the vessel quick on her helm, a noteworthy feature in a barge employed solely on inland water transport. The trials, it appears, were very successful: the apparatus proved itself not only capable of driving the barge on load draught at a fair speed, but it could easily take in tow two other loaded barges, making a total of about 100 tons deadweight. The initial cost is also comparatively small, as one equipment can easily serve a number of barges.

OBITUARY.

ALFRED DE ROTHSCHILD, C.V.O.—The death of Mr. Alfred Charles de Rothschild occurred at his town house, 1, Seamore Place, Mayfair, on January 31st. The second son of Baron Lionel Nathan de Rothschild, M.P.—the first Jew elected to the House of Commons—he was born in 1842, and educated at King's College School and Trinity College, Cambridge. He was associated with his brothers Nathan (afterwards Lord Rothschild) and Leopold as a partner in the firm of Messrs. N. M. Rothschild and Sons. He was also for more than twenty years a director of the Bank of England, and, until the war, Austro-Hungarian Consul-General. Lord Rothschild died in 1915 and Mr. Leopold de Rothschild in 1917. All three were Fellows of the Royal Society of Arts, and one of them, Lord Rothschild, was for some time a member of the Council. A man of cultivated taste, Mr. Alfred de Rothschild published for private circulation two volumes, with illustrations and descriptions, of his valuable art possessions. He was a trustee of the National Gallery and of the Wallace Collection. Last year he placed at the disposal of the Prime Minister, "for the benefit of the country," the woods on his Halton estate in Hertfordshire, 500 acres of which were planted with birch. He held the Legion d'Honneur, and had been a Commander of the Royal Victorian Order since 1902.

GENERAL NOTES.

THE MINERAL OIL RESOURCES IN THE BRITISH EMPIRE.—Some interesting facts about the production of mineral oil within the British Empire were given by Professor J. S. S. Brame, of the Royal Naval College, in a recent lecture before the London School of Economics. In the present circumstances such sources are specially valuable, as being less liable to interruption than those in foreign regions. By far the most important source of supply is Burma, which furnishes nearly three million gallons per annum. Assam and the Punjab also afford useful contributions, while among other regions may be mentioned Taranaki in New Zealand, Trinidad and Barbados, Canada, Egypt, Sarawak and British North Borneo. In Canada the output has unfortunately diminished during recent years. Within the United Kingdom the Scottish shale-oil industry is an important asset, and further possible sources in Norfolk and elsewhere are being examined. There are vast latent possibilities in the distillation of oil from the tar-fields of Athabasca, which extend over thousands of miles, and probably contain enough oil to last the world for 2,000 years. When the country is more fully developed, better transport facilities are available, and the cost of extraction can be reduced, these deposits may prove a very valuable asset to the Empire. At present, however, only about 3 per cent. of the world's production of mineral oil comes from the British Colonies and Dominions.

BANK MEETINGS.—Sir Edward H. Holden, at the annual general meeting of the shareholders in the London City & Midland Bank, Ltd., gave an interesting account of Germany's pre-war financial methods and banking law. He followed this up with an analysis of the financial position of the United States of America, and a description of the financing of the two "Liberty Loans." Out of these the United States Treasury arranged between April and December 31st, 1917, the following loans for the Allies: to Great Britain, £409,000,000; France, £257,000,000; Italy, £100,000,000; Russia,

£65,000,000; Belgium, £15,480,000; Serbia, £800,000; making a total of £847,280,000.—Mr. Walter Leaf (chairman), presiding at the annual general meeting of the London County and Westminster Bank, said that the shareholders had probably heard fears in some quarters that the great increase in Bank resources might form a strong temptation to the Chancellor of the Exchequer to help himself in some emergency by commandeering bank balances. That was not, in his opinion, a risk which deserved any attention. The Chancellor could gain nothing by such an operation, because he had got the whole increase already by a voluntary process. When they considered that the increase in cash at call and short notice was mainly lent to the Government through the Bank of England; that the great increase in bills discounted had gone direct into the Chancellor's hands in the form of Treasury Bills; and that the increase in advances had done so indirectly through the bank's customers' investments in War Loan, the shareholders would see that if he attempted to call upon the bank for anything in the way of a forced loan, it would not be possible for it to meet such a requisition except by taking from him with one hand what he was asking the bank to give with the other.

THE RÖNTGEN SOCIETY.—At the meeting of the Röntgen Society, held on January 1st, Mr. Carl Darnell read two papers communicated by Dr. Coolidge, of the General Electric Co.'s Research Laboratories, U.S.A. The first dealt with a new form of Coolidge tube, in which the anticathode consists of a block of copper faced with a small button of tungsten. This is fixed to a thick stem of copper which passes out through the glass neck of the tube, and terminates in a fin radiator. The anticathode is thus kept cool, and does not in consequence emit electrons, as in the case of the earlier Coolidge tube in which the whole of the anticathode speedily becomes red hot. The new tube, therefore, so completely rectifies current that when an alternating potential is applied only one phase of the current will pass. In the second paper, by Dr. Coolidge and Mr. Moore, the portable field X-ray outfit of the United States Army was described. A petrol electric unit supplies alternating current at 110 volts to a transformer arranged to give both high tension and heating currents for the new radiator type of Coolidge tube. For simplicity of control the tube is worked at a constant potential of 5-in. equivalent spark-gap, and the current is adjusted to 5 milliamperes for continuous running of the tube or 10 milliamperes for short periods. An electrically-actuated control on the throttle of the engine maintains constant output. The small size of the tube—3½ in. in diameter—enables a close-fitting lead-glass shield to be employed; this is made in two parts, and completely surrounds the tube, a suitable aperture permitting egress of the rays.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 13.—LORD LEVERHULME, "The Relations between Capital and Labour — Reasonable Hours, Co-partnership, and Efficiency."

FEBRUARY 20.—MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." SIR ASTON WEBB, K.C.V.O., C.B., R.A., F.S.A., F.R.I.B.A., will preside.

FEBRUARY 27.—SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

MARCH 6.—A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 13.—PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The ARCHBISHOP OF CANTERBURY will preside.

MARCH 20.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

Dates to be hereafter announced:—

MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

PERCY SHUTTLEWOOD, Ministry of Food, "The Food Situation in Germany."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

FEBRUARY 14. — SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces, "The Indian Hide and Leather Trade." The RIGHT HON. LORD ISLINGTON, G.C.M.G., D.S.O., Under-Secretary of State for India, will preside.

MARCH 14.—

APRIL 18.—ALFRED DICKINSON, M.Inst. C.E., "Water Power in India."

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 5. — GEORGE YOUNG, M.V.O., ex-Secretary of Legation, Lisbon, "Portugal as a Colonial Power."

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." Three Lectures.

February 18, 25, March 4.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 11 ... Engineers, Society of, at the Geological Society, Burlington House, W., 5.30 p.m. Presidential address by Mr. W. B. Esson.

East India Association, Caxton Hall, Westminster, S.W., 3.30 p.m. Mr. H. S. L. Polak, "Indian Labour Emigration within the Empire."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Sir Aston Webb, "The London Society's Map with its Proposals for the Improvement of London."

Electrical Engineers, Institution of (Local Section), Mining Institute, Newcastle, 6.45 p.m. Mr. F. G. C. Baldwin, "Telephone Exchange Transfers and their Organisation."

TUESDAY, FEBRUARY 12...Cold Storage and Ice Association, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Staff Sergeant-Major A. M. Wright, "Some Applications of Chemistry to the Frozen Meat Industry."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 6.30 p.m. Mr. T. J. Norman, "The Decorations and Furniture of the Royal Palaces."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Mr. R. G. Brown, "The Drama in Burma."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "The Problems of British Anthropology." (Lecture II.)

Electrical Engineers, Institution of (Local Section), 17, Albert-square, Manchester, 7 p.m. Professor E. W. Marchant, "Some Transient Phenomena in Electrical Supply Systems."

(Scottish Section.) 207, Bath-street, Glasgow, 7 p.m. Professor M. Maclean, "Kelvin as a Teacher."

(Yorkshire Section.) Philosophical Hall, Leeds, 7 p.m. Mr. E. C. McKinnon, "Large Batteries for Power Purposes."

WEDNESDAY, FEBRUARY 13...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Lord Leverhulme, "The Relations between Capital and Labour—Reasonable Hours—Co-partnership and Efficiency."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. E. A. Savage, "The Utilisation of the Data of the Automobile Industry through Bureaux of Information."

Biblical Archæology, Society of, 37, Great Russell-street, W.C., 4.30 p.m. Mr. W. L. Nash, "The Origin of the Mediæval representations of Weighing the Soul after Death."

Japan Society, 20, Hanover-square, W., 3.30 p.m. Admiral Sir E. R. Fremantle, "Reminiscences of Japan."

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Sir Arthur Newsholme, "The Problem of Tuberculosis under War and After-War Conditions."

THURSDAY, FEBRUARY 14...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Sir Henry Ledgard, "The Indian Hide and Leather Trade."

Royal Society, Burlington House, W., 4.30 p.m.

Faraday Society, Municipal School of Technology, Whitworth-street, Manchester, 7 p.m. Conference on "Electric Furnaces."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. Gosse, "Three French Moralists, and their Influence on the War—La Rochefoucauld." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.30 p.m. Mr. J. R. H. Weaver, "More about the Photography of Architecture."

Optical Society, at the Imperial College of Science, South Kensington, S.W., 8 p.m. 1. Annual Meeting. 2. Naval Instructor T. Y. Baker, "Reflecting Prisms."

Historical Society, 22, Russell-square, W.C., 5 p.m.

FRIDAY, FEBRUARY 15...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor E. H. Starling, "The Mechanism of the Heart."

Geological Society, Burlington House, W., 5.30 p.m. Anniversary.

University of London, Slade School of Fine Art, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture V.)

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m. 1. Annual General Meeting. 2. Mr. L. A. Legros, "Traction on Bad Roads or Land." 3. Mr. A. Amos, "Utility of Motor Tractors for Tillage Purposes."

SATURDAY, FEBRUARY 16...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Problems in Atomic Structure." (Lecture I.)

Automobile Engineers, Institution of (Scottish Centre), Technical College, George-street, Glasgow. Mr. D. Drummond, "Coal Oils."

REPORT OF THE AUDITORS TO THE SHAREHOLDERS OF THE LONDON CITY & MIDLAND BANK, LIMITED.

In accordance with the provisions of Sub-section 2 of Section 113 of the Companies (Consolidation) Act, 1908, we report as follows:—

We have examined the above Balance Sheet in detail with the Books at Head Office and with the certified Returns from the Branches. We have satisfied ourselves as to the correctness of the Cash Balances and the Bills of Exchange and have verified the correctness of the Money at Call and Short Notice. We have also verified the Securities representing the Investments of the Bank, and having obtained all the information and explanations we have required, we are of opinion that such Balance Sheet is properly drawn up so as to exhibit a true and correct view of the state of the Company's affairs according to the best of our information and the explanations given to us and as shown by the books of the Company.

London, *14th January*, 1918. WHINNEY, SMITH & WHINNEY, Chartered Accountants, *Auditors.*

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,404. VOL. LXVI.

FRIDAY, FEBRUARY 15, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 18th, at 4.30 p.m. (Cantor Lecture.) EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture I.)

WEDNESDAY, FEBRUARY 20th, at 4.30 p.m. (Ordinary Meeting.) MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." JOHN SLATER, F.R.I.B.A., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

TENTH ORDINARY MEETING.

Wednesday afternoon, February 13th; Mr. R. TOOTILL, M.P., in the chair. A paper on "The Relations between Capital and Labour" was read by LORD LEVERHULME.

The paper and discussion will be published in the *Journal* of March 1st.

INDIAN SECTION.

Thursday afternoon, February 14th; SIR CHARLES S. BAYLEY, G.C.I.E., K.C.S.I., in the chair. A paper on "The Indian Hide and Leather Trade" was read by SIR HENRY LEDGARD, late President, Upper India Chamber of Commerce, and Member, Board of Industries, United Provinces.

The paper and discussion will be published in the *Journal* of March 8th.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s.* each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, February 5th, 1918; The RIGHT HON. VISCOUNT GLADSTONE, G.C.B., G.C.M.G., G.B.E., in the chair.

The paper read was—

THE INDUSTRIAL RESOURCES OF THE UNION OF SOUTH AFRICA.

By C. DU PLESSIS CHIAPPINI,
Trades Commissioner for the Union of South Africa.

In dealing with the industries of the Union of South Africa in a short paper like this the difficulty at once presents itself of how to find room to make even a brief reference to the numerous trades and industries of the Union, old and new, great and small. The new and minor industries will, perhaps, constitute the most interesting subject-matter, and cannot therefore be excluded; but a review of the industries of South Africa would be incomplete without a reference to the problems of the present, and the great questions of the future, which will considerably influence the course of the development of agriculture, commerce, and industry within the Union.

The Union of South Africa embraces an area of 473,000 square miles, or nearly four times the size of the United Kingdom, and more than twice the size of Germany. It includes the former Colonies of the Cape, Transvaal, Orange Free State, and Natal.

The estimated population of the Union in 1914 was made up as follows:—

Persons of European descent . .	1,368,959
Natives and other coloured people	5,046,585
	6,415,544

Of the coloured people, about one million are already in a fairly advanced state of education and civilisation.

The country is governed by a constitution granted by the Imperial Parliament under the South Africa Act of 1909, in virtue of which each of the four Colonies became a Province of the Union. The legislatures consist of a Senate, a Legislative Assembly for the Union, and a Provincial Council for each Province.

The constitution of the Union affords freedom and protection to all, and security of property to landed owners and investors of funds.

The principal industries of the Union may be divided into three groups—namely, agriculture, mining, and manufacturing. I place agriculture first because to the people of South Africa it is by far the most important, and touches their interests in almost every direction; indeed this war has shown that there comes a time when the destiny of nations is consummated in the one word—"agriculture." Mining ranks next in importance, but it is clear that, when at some remote epoch the rich gold mines are worked out, agriculture and manufactures will be conspicuous as the two chief classes of industry in the Union. It must, however, be frankly acknowledged that the mining industry is the best customer to the agriculturist and the manufacturer, for not only has it done much to promote the development of agriculture, but the great progress made by the manufacturing industries is almost entirely due to the generous support of the mining industry; moreover, it cannot be denied that mining contributes the largest proportion to the State revenue, and that it is the industry which brought about most of the extensive railway developments in the Union.

In reviewing the position of these three groups of industries, one cannot help emphasising the fact that in all of them, especially agriculture and manufactures, great progress has been made during recent years.

The financial position of commerce and industry within the Union is sound, thanks to the wise and careful policy adopted by the leading banking institutions in the country.

Apart from gold and diamonds, the principal products of the Union are raw materials, which are required by the manufacturers in oversea countries, and foodstuffs. It is generally agreed that these important lines of produce will be in urgent demand after the war. The question as to what methods should be adopted to divert the raw materials and foodstuffs produced within the Dominions to the Home Country has been much discussed by leading statesmen, economists, and trade experts; and undoubtedly this is now a matter for serious consideration by the producers in the Dominions who desire to increase their production, and would like to see their goods sold and used within the Empire—a view conceivably shared by the manufacturers in the Mother Country, who, being equally concerned in turning the situation to good account, are anxious to re-establish their factories and again compete in the world's markets with their products. As this question of marketing is of paramount importance, both to the producer of raw materials and to the manufacturer, I cannot avoid referring to it in this paper, though I am loath to do so having regard to the fact that it is a very contentious matter. I am anxious not to side with one side or the other, and should any deduction be made from the comments I make in this paper, it must be clearly understood that these are only my private views. I have no knowledge of the views of the Government or the people of the Union of South Africa upon these questions; and, further, I have in mind only the raw products of the Dominions. My views upon the marketing of imported manufactured goods into the Dominions may be quite different. Each of these classes of trade creates different problems, and must be dealt with on its merits.

The position, as it appears to me, is that the British manufacturers, realising that there is going to be a great shortage of raw materials, and fearing keen competition from undesirable foreign quarters after the war, are considering ways and means of diverting these goods to the home markets. Various proposals have been put forward, but most of them have been demolished at the hands of public critics. To keep the raw materials within the Empire is the objective which all have in view—the producer as well as the manufacturer—and it will, I think, be ultimately achieved by adopting the straightforward policy of the "open road of commerce"—that is to say, the "line of least resistance," and by gravitation rather than by force or other means.

But whatever means may ultimately be decided upon for diverting the Empire's raw products to the Empire's markets, I sincerely trust that they will be of such a nature as will facilitate their transportation to the markets where they are most needed, and consequently will realise the best prices; this is a sure means of increasing the production of these much-needed products within the Empire. If the producers of raw materials see that their hard-won products are, for some reason over which

they have no control, realising lower prices than what similar goods are being sold at in other markets, their discontentment will grow as time goes on, and when patriotism gives way to materialism it is certain that means will be found to place their goods on the markets which offer the best prices.

If, therefore, the roads to all markets are left open, and at the same time special facilities provided by means of subsidies, or other form of State aid, for the transportation of raw materials or manufactured goods to the most-favoured markets, then neither the producer nor the manufacturer will have a valid reason to be discontented.

With the hope that I shall not be considered too critical, I would like to draw attention to the matter of the sale of our raw products in the United Kingdom and foreign countries previous to the war; and I trust that the British manufacturers will carefully consider the question, and thus place themselves in a position to use more of the raw products of the Dominions in the future than they have done in the past.

Before the war, Germany bought annually about 65 per cent. of the South African wool clip, the reason being that they had established plants known as "carbonising machinery" to deal with the vegetable matter in the wool; whereas the British manufacturer was inadequately equipped with this class of machinery, and could therefore not find use for our "burry" wool.

France, on the other hand, bought almost all the "short" wools produced in the Union, because the French manufacturers possessed improved "combing plants," which could best manipulate these short wools.

Then, again, Germany bought by far the greater portion of the South African hides, so I am told, because they are too light for the English market, and the same objection applies to Indian hides, almost all of which were also bought by the Germans.

Germany bought annually about 80 per cent. of the Natal wattle-bark, and notwithstanding that every effort had been made by the exporters and the Union Government to establish markets here, the British tanners, previous to the war, though acknowledging the good qualities of the bark, persistently refused to use it, alleging as their reason that they preferred their tannin material in the form of extract. These raw materials, to which I have referred, were not necessarily shipped direct to Germany, inasmuch as the bulk of them were actually bought at the London sales and reshipped to Germany.

If producers in South Africa are asked to make any special effort to direct their products to the home markets in the future, they will want some assurance that better means have been devised by British manufacturers to deal with the goods—or, in other words, that the products can be used here and are wanted.

Immediately previous to the war the South African producers and shippers were well provided with excellent lines of steamers and had little to complain of, but the question of providing shipping after the war to meet the greatly increased production of raw materials and food products—and especially adequate cold storage accommodation—is a matter for very grave consideration, and as such it is receiving the attention of the Governments concerned. It is in this respect that assistance and co-operation from this country may be opportune. My advice to those who are considering the much-discussed question of "trade after the war" is—See to your shipping; it is the man who sends the ship who will get the goods, and the need for shipping will be such that the question of the "flag" will not stand in the way of the goods which must be shipped. Therefore, if we want "trade with and in the Empire," we must help each other to provide British ships for the Empire's sea routes, and we must do that soon.

AGRICULTURE.

Agricultural and pastoral pursuits have made considerable progress during the six years previous to the war, as the following figures of the values of agricultural and pastoral products exported from the Union during the years mentioned will show: 1907, £7,363,000; 1913, £12,239,000. Unfortunately the figures for 1917 are not yet available; if I were able to give them it would be seen that even under war conditions great progress has been made.

The Union Government possesses a most efficient and well-administered Agricultural Department, composed of several "divisions," the chief of which are agricultural education, sheep, veterinary research, horticulture, viticulture, tobacco and cotton, dairying, botany, chemistry, and entomology. Besides these, there are other important institutions relating to agriculture but independent of the Agricultural Department—namely, the Departments of Forestry, Irrigation, and the Land Bank.

The development in agriculture is largely due

to the attention given to the important question of irrigation, great success having been achieved in this direction, particularly in regard to the diversion of storm-water from the intermittent rivers during the short periods in which they flow; thus the water which used to rush from the inland plateaux to the sea is now utilised and serves to irrigate large tracts of rich loamy soil in the dry arid regions, which are thus made to produce one of the most valuable agricultural products, namely, lucerne, which stock-farmers prize more than any other field product in the Union.

Farming in South Africa has many advantages; and because of the beautiful climate, the healthy outdoor exercise, besides the opportunities for investment and profit which it affords, it has attracted the leading men in the country. It is the ultimate goal of judges, lawyers, other professional men, and merchants. It is the source of much pleasure to the wealthy; it is the boast of the politician; while it always remains the serious means of earning a living and sometimes of making a fortune to the many thousands of hardworking, diligent farmers.

The agriculturist in South Africa is prosperous and thrifty; as a rule he owns the land he works on; he holds a good social position; every opportunity is given him for the education of his children, of which he takes full advantage; he gives great attention to his calling, and is regarded as being progressive, except by those who know nothing about farming.

A great future is assured for the agricultural industry of South Africa, not only the part comprising the Union, but also the adjoining British and foreign possessions.

Wool.

The principal agricultural product is wool. The total value exported during 1907 was £3,128,927; in 1917, £8,782,280. The quantities exported were, in 1907, 97,711,000 lb., and in 1917, 117,657,000 lb. There are 34,000,000 sheep in the Union, of which approximately 9,000,000 are not wool-bearing, but are produced chiefly for their excellent mutton, and because they can resist droughts well and mature quickly. The wool-bearing sheep are chiefly merinos, the breed of which has greatly improved during recent years. The grading and the skirting of the wool for export has also shown remarkable improvement.

Mohair.

This is also an important industry. The Angora goats were originally imported from Asia Minor under special licence from the Turkish Government, and great care was taken in the selection and breeding of the animals, with the result that a very fine quality hair is produced from these thoroughbreds.

The average export in normal times amounts to about 20,000,000 lb., valued at close upon £900,000 per annum. As mohair materials are not essential for Army purposes, the quantity of mohair imported into the United Kingdom during the period of hostilities has diminished; but in normal times South Africa supplies the English market with about 60 per cent. of its total requirements, whilst Turkey supplied the balance.

Hides.

The output of hides in the Union has considerably increased. During 1907 the total quantity of hides exported was 7,456,000 lb., valued at £203,000, and in 1917 the total quantity exported was, approximately, 18,000,000 lb. weight, valued at about £837,000.

Skins.

Sheep and goat skins from South Africa are much prized by glove-makers and manufacturers of leather goods. In 1907 the exports were 24,418,000 lb., valued at £743,000, and the average annual exports since 1913 were about 42,000,000 lb., valued at £1,600,000.

Maize.

Maize has been produced in South Africa since the time of the earliest white settlers, but a serious export trade was not initiated until about the year 1908. During the two preceding years experimental shipments were made under the auspices of the Union Government, and it was then found that the maize, although sound and dry, was "mixed" and not of the type required on these markets. These faults were, however, quickly remedied when they were pointed out to the Government and the producers. New types of maize were introduced, and large quantities of improved seeds were produced on the Government experimental farms and distributed to the growers, with the result that South Africa now exports the finest quality maize to these markets, and the maize is further appreciated because of its dryness in comparison with maize from other countries.

Greater confidence was also established in these markets by the system of Government grading inaugurated, which has been strictly carried out to the satisfaction of the shippers and importers, thus considerably enhancing the success of the maize export trade.

In 1908 the exports amounted to 463,000 bags (200 lb. each), which was increased to approximately 2,200,000 bags in 1917, valued at the ports in South Africa at about £1,540,000.

Ostrich Feathers.

The production of ostrich feathers in South Africa was one of the most successful of the agricultural pursuits in the Union previous to the war. It is an industry peculiar to South Africa, and owes its success to the great care given by the breeders in producing the types of feathers most desired by the markets of the world. Within a comparatively short period the quality and desired shape of the feathers had been vastly improved by the method of breeding by selection, in recognition of the fact that the prime feathers of the domesticated ostrich are of much greater value than those yielded by the bird in its wild state.

South Africa had what was practically a monopoly of the world's markets, having produced about 85 per cent. of the total requirements of the feather trade.

Immediately previous to the war the fashion in ostrich feathers greatly declined, and the trade is now at very low ebb; but as ostrich feathers have been fashionable more or less for forty years, and previously were in use for decorative purposes for nearly 2,000 years, there can be little doubt that when more normal conditions prevail the ostrich feather will again come into vogue, thus restoring the industry to its former state of prosperity. The largest output of feathers was during the year 1913, when 1,023,000 lb. were exported, valued at nearly £3,000,000.

Fruit.

Most of the well-known varieties of tropical and sub-tropical fruits have been cultivated in South Africa since the advent of the first white settlers, but it has only been within the last fifteen years that fresh fruit has been extensively produced with a view to exportation.

The principal varieties of fruit exported are grapes, pears, plums, peaches, apricots, and nectarines. These varieties are grown within one hundred miles of Cape Town.

Great progress has also been made in the cultivation of oranges for export. Many hundreds of thousands of trees of the most suitable and best varieties have been planted. Oranges are produced in many parts of the Union, particularly the Transvaal and the Cape Province. Substantial profits have already been made by orange-growers. I consider that this line of fruit-growing offers great possibilities for the future.

Pineapples, which should also become a big commercial line of fruit, are principally grown in the districts of Albany and East London in the Cape Province, also in the Natal Province. It is anticipated that a large and profitable export trade will be established in this fruit when more normal conditions prevail.

The Union Government has given particular attention to the fruit export trade. Official graders have been appointed at the ports to grade and inspect the fruit before shipment, and qualified packers are sent to all the fruit-growing districts when needed, to instruct the growers in the most up-to-date methods of packing fruit for export, with the result that fruit-growers in South Africa have attained great proficiency in the art, and they now have little to learn in that respect.

The fruit export trade arrived at its highest point immediately prior to the war. Since then the export of fresh fruit has practically ceased, owing to the lack of cold-storage accommodation in the steamers.

During the year 1914, 526,000 boxes of fruit (deciduous and citrus) were exported to this country. It is confidently expected that when more normal conditions prevail, and sufficient cold-storage space is provided in the steamers, the export of deciduous fruit will exceed 1,000,000 boxes per annum, and that the export of oranges will be about equal to that amount.

There can be no doubt that South Africa's fruit export trade will, in time, become one of the country's chief industries.

Dried Fruit.

Dried fruit is another export trade which has a splendid future, and rapid strides have been made in improving the quality and packing of fruit for these markets. An export trade, although at present a small one, has already been started in raisins, prunes, and apricots. For several years past small experimental shipments have been made to the United Kingdom, and the opinions and criticisms of the dealers were carefully noted and reported to the producers, who readily adapted their produce to the requirements of these markets. Developments followed, and during the past year approximately 380 tons of dried fruit, chiefly raisins and prunes, were exported from South Africa to the United Kingdom.

Wattle-bark.

The production of wattle-bark is one of the chief agricultural industries in the Natal Province. This bark, which is a splendid tanning agent, and is stripped from the black wattle tree (*Acacia mollissima*) indigenous to South-eastern Australia, was introduced into Natal about thirty years ago, and since its introduction an industry of first importance has been established.

The cultivation of wattle trees has proved very remunerative to the Natal farmer. The trees are ready for felling and the bark is stripped off when they are about six years of age. The grower usually cuts his trees in rotation, taking six or seven years to go through his plantation, when he commences again *ab initio*. The trees are self-sown, and, with a little care, again come to maturity in the usual time.

At present there are about 160,000 acres of land devoted to wattle-growing, and the annual yield is approximately 65,000 tons of bark, which output is expected to increase considerably. The average price realised for dried bark, bagged and chopped, is from £5 to £6 per ton at Durban. The export of bark in 1907 amounted to 54,500,000 lb., valued at £139,400, and during 1917, 93,532,000 lb., valued at £225,722.

Wattle-bark contains from 28 to 30 per cent. of tannin acid. One of the most valuable by-products is the timber, which is in great demand at the mines for pit props, the sale of which, in some instances, more than recompenses the growers for the cost of producing the bark.

Prior to the war very little wattle-bark was used by the English tanners, and practically the only market was in Hamburg; but since the outbreak of hostilities the bark has been used in England with considerable success.

Shortly after the war broke out, some enterprising persons established factories in Natal for the manufacture of wattle-extract; two factories are now producing the extract, and the new industry has proved to be very remunerative. The extract is of high tanning value and realises good prices on these markets.

It is anticipated that the bulk of the bark produced in Natal will, after the war, be consumed by the local extract factories, and that more of these will be erected.

Frozen Meat.

It is anticipated that the export of meat from the Union will become one of the most important industries of the future. The war has undoubtedly given a great impetus to this trade, but it must be remembered that the matter was much discussed in the Union and seriously taken in hand by the Government previous to the war, because it was then seen that, while the meat supplies of the world were gradually diminishing, the number of cattle and sheep in the Union was increasing. At one time it was feared that the ravages of the East Coast fever would seriously hamper the development of cattle-farming; but, thanks to the energies of the Director of Veterinary Research, and to the system of compulsory dipping, the East Coast fever is being checked, and the number of cattle in the Union is multiplying rapidly. Southern Rhodesia opportunely came forward with large contributions of cattle, which, I frankly admit, considerably helped to swell the supplies shipped from Union ports during the past year. It is generally acknowledged that cattle-ranching in Rhodesia has a great future.

The class and breed of cattle have been immensely improved during recent years, and I consider that this is largely to be attributed to the generosity and public-spiritedness of the Union Castle Steamship Co., for having undertaken to carry pedigree stock free of charge from Europe to the Union. Great use has been made of this concession, and since it came into operation many hundreds of valuable pedigree animals have been shipped to South Africa.

The total number of cattle in the Union is estimated at 8,000,000, and, as previously stated, the total number of sheep is 34,000,000.

It is interesting to note that New Zealand, with a consuming public numerically slightly below that of South Africa, and with only 24,000,000 sheep, is the biggest exporter in the world of mutton and lamb.

South Africa has, however, now determinedly entered into the market with the exportation of beef. In this connection it may be pointed out that only five years ago South Africa was still importing meat, whereas the total exports of beef from the Union during 1917 exceeded 21,000 tons, valued at £1,160,000 at the ports of shipment.

Great attention has recently been given to the establishment of modern abattoirs and packing-houses, and while it has not been possible for the promoters of these schemes to obtain the machinery during the war, preparations are being made for setting up plants immediately hostilities cease, much experience having been gained during the war which will be useful in

the future. Plans are also being matured for the erection of meat-canning factories, which are a necessary adjunct to a meat export trade; moreover, there is always a considerable market in South Africa for canned meat.

Butter.

This is another agricultural industry which has made rapid progress during recent years; the success which has been achieved is largely due to the untiring efforts of the dairying division of agriculture, which has encouraged the formation of dairies and creameries in the pastoral districts of the various Provinces. At present there are fifty-two creameries in the Union.

The annual production of butter by established dairy factories in the Union is about 14,000,000 lb. The export of butter to the United Kingdom for 1917 was about 54,200 cases.

Eggs.

The export of eggs is also a new undertaking to which the Government has given great attention. Government graders have been appointed at the ports, and the best known systems of packing and grading have been adopted, with the result that the eggs are arriving on these markets in excellent condition.

To illustrate the growth of this new trade, I submit the following export figures: During 1914, 2,300 cases; in 1916, 24,000 cases. (A case contains thirty dozen eggs.)

The question of the export of liquid eggs is also receiving the attention of the shippers, and quite recently an experimental consignment was made of liquid ostrich eggs, which was favourably reported upon by trade experts.

Cotton.

For the past ten years the Union Government has given much assistance to farmers in order to encourage the production of cotton in the Union, with the result that the industry has made satisfactory progress. The cotton produced is of good quality, and meets with a ready sale on these markets.

According to the latest figures there are approximately 5,200 acres under cultivation in the following districts:—

Rustenburg	3,000 acres.
Waterberg	2,000 ,,
Zoutpansberg	100 ,,
Natal	100 ,,

In addition to these there are one or two small cotton areas in the Middelburg district, the Orange Free State, and the Cape Province. The annual yield for the season 1916–17 was 700,000 lb. seed cotton and 233,000 lb. of lint.

Throughout the Union there are considerable areas where the soil and climatic conditions are suited for cotton cultivation.

The question of dealing with the by-products of the cotton is receiving serious attention; two small plants have already been erected to crush the seeds for oil and oil-cake.

Fishing.

The fishing industry of South Africa is a very important one. The seas round the coasts of the Union abound with many varieties of good quality fish. The types vary to some extent in the waters of the different parts of the coast.

Formerly the industry was in the hands of the Malays and coloured people, Cape Town being the principal centre; but subsequently Italian fishermen established themselves and almost monopolised the industry at some of the ports.

Later on, however, steam trawlers, of which there are now nine, were introduced by one of the large English fishing companies, and their operations have proved to be most profitable.

As the result of facilities offered by the railways, fresh fish in large quantities is carried far inland to every part of the Union by means of refrigerator cars, and it is a pleasant surprise to the traveller, a thousand miles inland, to be served with fresh deep-sea fish in the railway dining saloons, and in the hotels even of the small country villages.

The big inland towns like Johannesburg, Kimberley, and Pretoria have become profitable markets for the fishing industry.

A most important section of the fishing industry is the canning of crayfish or "spiney lobster." There are seven factories engaged in this industry, and they are situated in the neighbourhood of Cape Town and at Saldahana Bay. The quantity exported to the United Kingdom during the past year was, approximately, 1,750,000 lb., valued at £150,000.

A considerable quantity is also consumed locally. The industry, as a whole, has proved to be a most profitable one.

Whaling is also an important section of the fishing industry, and several companies and firms have established whaling stations at different points along the coasts of the Union. The exports of whale oil during the year 1916 amounted to 901,796 gallons, valued at £60.295.

The fishing industry generally is controlled by Boards of Fisheries under the direction of the Minister of Industry, who is advised by competent biologists. In recent years regulations have been framed, defining the seasons and

restricting the areas, as well as the size of the different types of fish which are permitted to be caught on the various fishing-grounds.

MINING.

In point of value mining is the most important industry in the Union at present. The gold and diamond mines of the Union are world-famous, and contribute by far the largest amount to the total output of minerals; but coal-mining, which has rapidly developed in recent years, is of the greatest material value to the country. The total value of the mineral output of the Union in 1916 was £50,593,000.

There are nearly 316,000 persons employed in the mines of the Union. This does not, of course, include the large outside population residing in mining towns and along the reefs, who are living indirectly on this prosperous industry. Of the number of employees in the mines, about 32,000 are whites and about 284,000 natives.

The annual value of stores consumed on the mines is approximately £14,000,000 per annum, of which more than half consists of agricultural products and goods manufactured within the Union.

The total production of gold in South Africa since 1868 up to date amounts approximately to £545,000,000 in value. South Africa contributes annually about 41 per cent. to the world's output of gold.

Though gold was being mined at Barberton, Pilgrim's Rest, and other parts of the Transvaal for many years previously, it was only in 1886 that the Gold Reef was discovered, which has alone contributed more to the world's output than any other gold-producing country in the world—I refer to the Main Reef of Witwatersrand. It is most remarkable that in comparison with the gold reefs of Australia, New Zealand, India, and the United States of America, it is the lowest in yield per ton; but owing to the consistency of the sedimentary deposits and the extraordinarily even distribution of the gold, it forms a payable mining proposition and a safe and profitable investment for capital.

The present gold production is at the rate of about £40,000,000 per annum, practically all of which is produced in the Transvaal. The average yield of ore mined in 1916 was 26*s.* 4*d.* per ton. The value of the yield is gradually decreasing; in 1910 it was 28*s.* 9*d.* per ton.

The total capital invested in the gold mines of the Union, practically all of which are in the Transvaal, is £82,373,000. The net profits of the mines amount to about £9,000,000 per annum, while the annual dividends on the share and debenture capital amount to about £8,000,000 per annum.

Diamonds.

Diamonds are the next most important mineral product of the Union; the mining of which in the past brought great prosperity to the Cape Colony during a period when it was most needed.

The first diamond was accidentally found in the district of Hopetown, in the Cape Colony, in 1867. In 1870 more diamonds were discovered on the banks of the Vaal River. Rapid progress was then made in the discovery of diamonds, not only along the great rivers—which are still known as "river diggings," and which still yield a fair proportion of the valuable stones—but deposits were subsequently discovered on the borders of the Orange Free State, which was then a portion of practically free native territory occupied by Griqua tribes. It was here that the De Beers, Bultfontein, and Kimberley mines and other valuable deposits were found in close proximity to each other.

These mines are now all worked by the De Beers Diamond Mining Company, which is the greatest concern of its kind in existence.

Mines were also discovered in the Orange Free State, some of which have proved to be very profitable.

In 1902 the Premier Diamond Mine was discovered in the Transvaal and rapidly developed; it has since become the second greatest producer of diamonds in the world, whilst the largest stone in the world, known as the "Cullinan Diamond," which weighed 3,025 carats, or nearly 1½ lb., was found in the mine.

The output of diamonds is sold in virtue of an agreement between the producing mines and a syndicate, for the purpose of regulating and controlling the prices. It has also been found necessary by the mines to regulate their output according to the demand.

The largest annual output was in 1913, when 5,503,000 carats were produced, and the value of diamonds exported amounted to £12,016,525.

According to available records the value of the diamond output to date since the earliest records have been kept, is approximately £178,000,000.

From the latest figures the number of persons employed in the diamond industry are 2,627 whites and 17,563 natives; whilst the alluvial diggings employ 2,899 whites and 13,666 natives.

Coal.

From a commercial and industrial point of view coal-mining is the most important of the mineral industries in the Union. It is of comparatively recent development, inasmuch as, not many years ago, South Africa imported coal for the working of machinery and for the bunkering of ships calling at the ports.

It is rather an extraordinary geological coincidence that coal should have been discovered in close proximity to the Main Reef at the time when that important gold-producing area was discovered, and thus materially helped in the development of that great industry.

The coal-mines of the Union are situated throughout the four Provinces, the Transvaal being the largest producer. The mines in that Province are situated in the district of Middelburg, also east of the Witwatersrand and in the Ermelo and Zoutpansberg districts.

The coal-fields in Natal are the next in importance, the principal coal-producing area in that Province being the Klip River district.

In the Orange Free State the coal-fields are situated chiefly in the north and north-west areas of the Province, and in the Kroonstad district.

The coal-fields of the Cape Province, which are the oldest in the Union, have not developed to any extent.

There are also undeveloped coal-seams in Natal and the Transvaal, and it is agreed that only a very small portion of the coal deposits of the Union have so far been exploited, and that the industry is capable of considerable developments for an indefinite period.

The bunkering of coal has become an important factor in the industry, and the South African ports have, as a result, become ports of call for many steamers passing along the highways of the Southern Seas.

The following figures will show the quantities and value of coal produced and sold within the Union during 1916:—

Province.	Tons (2,000 lb.).	Value. £	Per ton. s.	d.
Transvaal . . .	6,136,913	1,382,680	4	6·07
Cape	41,752	24,092	11	6·49
Orange Free State	762,576	198,699	5	2·54
Natal	3,066,261	1,134,194	7	4·77
	10,007,502	2,739,665		

The figures given below show the quantities of coal exported from and bunkered at South African ports and produced from mines within the Union during 1916:—

Province.	Tons of Coal Bunkered.	Tons of Coal Exported.
Cape Town	559,331	7,453
Port Elizabeth . .	124	—
East London . . .	98	—
Durban	1,224,091	159,016
Delagoa Bay . . .	379,313	399,167
Knysna	1,305	—
	2,164,262	565,636

Much attention has recently been given to the possibilities of the production of the by-products of coal, which promises to open up new fields of industry within the Union.

Copper.

The mining of copper is one of the oldest mining industries in the Union. It was at first carried out entirely in Namaqualand, a portion of the Cape Province. Subsequently discoveries were made in the Zoutpansberg district in the Transvaal, and in other parts of that Province.

Since the earliest date of existing records, the total quantity of copper produced within the Union is valued at over £22,000,000 sterling.

The following figures show the output of the Union during 1915:—

Province.	Tons (2,000 lb.).	Value. £
Transvaal (per cent. of pure metal, 43·38). .	14,996	525,106
Cape (per cent. of pure metal, 44·48) . . .	13,973	517,208
	28,969	1,042,314

Cement.

The manufacture of cement has become a very important industry in the Union, and is of particular commercial benefit to the country, especially now that shipping space is so limited.

Quite recently nearly all the cement used in the Union came from overseas, but now practically no cement is imported. An excellent quality of cement is manufactured in the

Union, the largest factory being the Pretoria Portland Cement Company, which alone produces nearly half a million casks of cement per annum. The raw material is drawn almost entirely from the district of Pretoria. About 200 tons of gypsum, which is supplied by farmers in that district, is annually consumed by this factory.

Another important cement works is the Whites South African Cement Company on the Vaal River.

The cement supplied by these companies is now accepted by Government contractors for the construction of huge concrete railway bridges, harbour works, and many other substantial structures, and has to conform strictly to specification and tests.

Many other minerals are also produced in the Union. Some of these are developing into important industries.

The following figures show the values of the minerals produced during 1916, to which I have not previously referred to in this paper:—

	£
Tin	339,571
Silver	106,311
Asbestos	83,070
Graphite	1,780
Magnesite	1,766
Antimony	15,292
Zinc	5,202
Corundum	7,762
Mica	1,185
Iron Pyrite	8,019

MANUFACTURING INDUSTRIES.

South Africa, like all other countries, possessed industries from the earliest times. These industries were, however, more or less of a domestic nature—*e.g.* small corn-mills, harness factories, cart and waggon factories, tanneries, etc., and catered only for some of the wants of the localities in which they were situated.

For a long time the mining industry attracted all the attention of the capitalists and the enterprising, while the more settled section of the communities devoted their attention to the development of agriculture, which also offered a profitable outlet for capital, labour, and energy.

But there has been a great awakening; the times and conditions have changed; much capital has been invested, and factories have followed factories throughout the Union; up-to-date plants have been erected everywhere, while experts and scientific men, and managers and foremen of great practical experience have been brought from manufacturing centres in other countries, and many experiments have been made, not without losses, and valuable experience was gained—all of which are necessary when industries are being established in new surroundings. Now, however, in several lines of manufactures considerable success has been achieved, and there is no question that the manufacturing industry has become an important factor in the economic welfare of the Union.

Long before the war, great progress was made in this direction, but since the war a considerable impetus has been given to local industries, insomuch as it was found to be most difficult to import the classes of manufactured goods as in normal times. Necessity being the mother of invention, these very difficulties have been turned to good account, to the lasting benefit of the country.

From the following figures disclosed by the recent Industrial Census, giving the value of the products at the periods mentioned, of the factories in the Provinces and the Union, it will be seen that, after a period of thirteen years, the value of the output of the factories has nearly doubled:—

1904.	£
Cape	9,040,579
Transvaal	6,471,082
Natal	4,076,088
Orange Free State	977,645
Total	£20,565,394

1917.	£
Cape	14,761,000
Transvaal	13,731,000
Natal	9,314,000
Orange Free State	1,885,000
Total	£39,691,000

The amount of capital invested in industries and in factories in the Union and in each Province is returned as follows:—

	£
Cape	14,941,000
Transvaal	17,533,000
Natal	10,657,000
Orange Free State	2,334,000
Total	£45,465,000

The following figures show the number of

persons of different races employed in the factories of the Union:—

White	Male	34,279
,,	Female	4,564
Natives	Male	33,855
,,	Female	383
Asiatic	Male	10,081
,,	Female	1,106
Other coloured	Male	11,839
,,	Female	3,327
Total	Male	90,054
,,	Female	9,380
Grand total		99,434

The returns also show that the wages paid annually to the white persons engaged in factories are £6,633,000, and to all coloured persons, £2,148,000—a total of £8,781,000.

The following tables, showing the number of different classes of factories in the Union in 1917, may be of interest:—

The Government control of matters connected with manufacturing industries is vested in the Minister of Mines and Industries, and is administered by the Industries Section of that Ministry.

An advisory Board, presided over by the Secretary for Mines and Industries, consisting of ten members who have knowledge of the mining, agricultural, industrial, and commercial problems, has been constituted; also a scientific and technical Advisory Committee composed of qualified scientists drawn from the principal scientific institutions and centres of learning in the Union.

Because of the high rates of shipping freights which are likely to prevail for several years after the war, South Africa will, in the near future, offer greater advantages for the investment of capital in industrial enterprises than ever it did in the past.

The enterprising manufacturer or investor who erects a factory in South Africa to utilise the raw materials produced in the Union, will

NUMBER OF FACTORIES.

find that a large margin of protection against the imported article will be afforded to him if the cost of freight for the export of the raw materials and the freight on the imported manufactured article is reckoned; besides which South Africa now has an ample supply of coal at reasonable rates, and a plentiful supply of cheap unskilled labour, which has vastly improved in recent years and has become more suited for factory labour.

With regard to markets for the manufactured goods in South Africa, it must be pointed out that as civilisation advances amongst the huge native populations in the Union and the adjoining British and foreign possessions, so the demand for certain classes of manufactured goods will increase; besides which the wants of the rich mining and the extensive agricultural communities are worth catering for.

I will now comment briefly on some of the more important industries of the Union.

Corn-mills.

Amongst the older industries, corn-mills have recently been much improved. Modern machinery has been put up to deal with maize and oats and other South African cereal products. The maize farina, such as semolina, flaked maize, etc., prepared by these mills, is of the highest quality and forms excellent household foods; while, thanks to the dryness of the climate, the oatmeal produced in the Union is of better quality than that produced in other countries where the climatic conditions are not so favourable.

Boot Factories.

There has been considerable development in the boot-manufacturing trade, and several modern factories are now working successfully on quite a large scale.

During the war large Army contracts for the requirements of the South African troops operating in West and East German territories were successfully carried out, and some of the South African boot factories sent samples of their goods to the War Office here with the request that they should be allowed to tender for the requirements of the Imperial forces, subject to compliance with the War Office specification, but their offer was not accepted.

Leather.

The tanning industry of the Union has made rapid progress during the past few years, and a good type of both sole and upper leather is now being produced.

There are at present about twenty tanneries in the Union, and the output of leather for 1917 is valued at approximately £500,000.

The industry is sure to develop substantially in the future, and there will be plenty of opportunities for the investment of additional capital. In this connection it should be borne in mind that the raw materials used in the tanning trade are produced in large quantities within the Union. I refer to hides, sheep, and goat skins. and to Natal wattle-bark and extract, the latter being one of the best tannin agents used by tanners. Besides these advantages we have also cheap labour, reasonable cost of living, and low taxation.

Small shipments of leather from the Union were made to the United Kingdom during the early part of last year. But later the South African tanners were refused permits to ship their leather to these markets.

Explosives.

The manufacture of explosives is an important industry. Besides the Cape Explosive Works, which are conducted on a very large scale in Somerset West at Cape Town, there are also two large factories established by well-known English firms operating in the Transvaal and Natal.

Wine.

One of the oldest industries of South Africa is that of wine-making. The earliest Dutch and Huguenot settlers, as far back as 1688, commenced planting vineyards. During the eighteenth century Cape wines, principally of the types known as "Constantia," were famous on the English market, their introduction being primarily due to the energy of the well-known firm of Messrs. Gilbey, Limited. In 1861, however, in consequence of the equalisation of the import duties on wines entering the United Kingdom, Cape wines failed to maintain their footing on the London market in competition with wines from other countries, and a comparatively large export trade was summarily almost extinguished.

The Western Province is unique in South Africa as a wine-producing region, and it must always remain so, seeing that it is only there that the climatic conditions are found which are required for the successful cultivation of grapes for wine-making. About 90 per cent. of the grapes produced in South Africa are grown in the Western Province, and within 150 miles of Cape Town.

The annual production of wine in the Union

is between four and five million gallons; about half of this is converted into brandy, for which the most modern stills have now been erected. The quality of South African brandy has vastly improved, whilst the production of the older types of brandies, which are not favoured in the wine trade, is now discouraged by the Government, the excise duty on the latter being considerably higher than on the brandy produced with modern stills.

Notwithstanding the many setbacks experienced, the industry is very prosperous. The Government has given every possible assistance to the wine-growers: some years ago well-known experts were engaged from other wine-producing countries of the world in order to instruct farmers how to improve the many types of wines. More recently South African students were sent to wine-producing countries in Europe to acquire proficiency, and they have returned to fill the place of experts in the wine trade. Important results have been achieved, and Cape wines are now of a much higher quality, and, further, they can be produced cheaply.

Had it not been for the shortage of shipping space during the past three years large quantities of wine would have been brought to this market.

Meantime, however, a highly successful commencement has been made by one of our most progressive firms of Colonial wine merchants to re-establish Cape wines on this market, and I sincerely hope that before long the trade will be firmly established.

Sugar.

One of the most important industries closely allied with agriculture is the production of sugar from cane. The output of the Natal sugar industry previous to the war was estimated at about 120,000 tons per annum. The output for 1917 is valued at £3,000,000 sterling.

The area of sugar-cane under cultivation is approximately 61,300 acres, extending along the coast-line of Natal, north-east towards Zululand, and south-west towards the Transkai border.

There are now about thirty-four sugar-mills and one large refinery in the Natal Province.

The labour employed consists chiefly of natives and Asiatics, and the supply is quite plentiful.

The industry is a fairly old-established one, but some years few ago a considerable impetus was given to it by the Government opening up land in Natal and Zululand, and establishing the central mill system.

Each year the area under sugar-cane is increasing, and it is expected that in the near future sufficient sugar will be produced to allow for a surplus to be exported.

Tobacco.

The tobacco industry is widely followed throughout the Union, and large areas of land are now devoted to its cultivation.

There are several Government tobacco experimental stations in the Union under the control of expert tobacco planters. Knowledge gained at these stations is imparted to the tobacco growers in those areas.

There are many commercial types of tobacco produced within the Union. The bulk of the trade consists of the manufacture of rolled tobacco, which is largely used by the farmers and the natives for pipe-smoking, the inferior classes being used for "sheep dip" and disinfectants. A big trade is also carried on in cut tobacco, the centre of which is Rustenburg, from where the famous "Magaliesberg" tobacco comes. This is a pipe tobacco of very high quality, and is much prized by those who are used to smoking it.

Turkish tobacco of very high quality is also produced, the centre of production being in the neighbourhood of Paarl and Stellenbosch, in the Western Province of the Cape, where nearly 500 acres of land are annually planted with this type of tobacco. Samples which were sent to this market were submitted to the greatest experts, who declared that the South African Turkish tobacco is the nearest in quality to tobacco produced in Turkey.

There are large tobacco and cigarette factories in the Union, especially in Cape Town, where huge quantities of cigarettes and tobacco are manufactured and put up under well-known brands, which supply the markets of the Union and the adjoining British and foreign territories. The value of the output of these factories for 1917 is estimated at £1,000,000.

Sundries.

Other trades which also have made much progress are candle and soap factories, which have been erected by well-known old-established English manufacturers. The present annual outputs of these industries are valued at £625,000 and £900,000 respectively.

The number of bacon and ham factories has

increased, and much improved the quality of their products.

Biscuits, cakes, sweets, and confectionery factories, have also been established in different parts of the Union, and even before the war their products could compete in quality and price with the imported articles.

Jam and fruit-canning factories have been successfully established, and fairly large quantities of South African jams have been shipped to these markets during the past year, and about 3,000,000 1-lb. tins were supplied to the War Office. The output of the jam factories in 1917 is estimated at £318,000.

Many other classes of industries are also being developed, and factories are now working and producing such articles as chloride of lime, carbide, iron (smelted from local ores), wattle-extract, glass bottles, alcohol, motor fuel, sulphate of ammonium, asbestos manufactures, tin, white arsenic, starch produced from maize, antimony, canned meat, chicory, and toys.

Railways and Harbours.

A paper dealing with the industries of South Africa would not be complete without a reference to our excellent system of railways, with which are associated the docks and harbours of the Union, because they fall under one administration. The people of South Africa are proud of their railways, not only because they are a great national asset, but also because they are well managed and afford comfort to the traveller and facilities to the producer and the trader.

The railways are the means of opening up and developing large areas of land which formerly produced very little, and are useful as a means of assisting in the establishment of new export trades by carrying the products from the far inland parts to the coast at much reduced rates.

The goods and passenger rates compare favourably with almost any railway in other parts of the world, and the accommodation and attention afforded to passengers for long-distance travelling surpasses in comfort that which is provided by few railways in other countries in comparison with the cost of the fares.

The Union possesses first-class docks and harbours at the different commercial ports which are fitted with all modern appliances, and which will accommodate and cater for the requirements of large steamers up to about 15,000 tons burden. The rates for coal and water are low, and the dock dues are not excessive; in fact, the charges are fixed with a view of attracting steamers to ports of the Union.

Position at end of 1916.

Total open mileage of South African railway lines . . . . (miles)	9,419
Total capital invested in the Government railways	£ 92,063,504
Surplus of earnings over working expenditure (not including interest on capital)	4,365,000
Capital expenditure on harbours . . .	10,200,167
Loss after paying interest on capital .	39,280

Conclusion.

In conclusion, I have to say that, in emphasising the prosperous position of the Union of South Africa, I have in no way overstated the case. It may be said that the enhanced export figures are due to the high prices of the produce. This is correct with regard to some lines, but against this I will point out that there are several classes of products for which no shipping space could be found during the war, and of which large quantities are still awaiting shipment in South Africa, whereas, in other cases, especially in the case of fresh fruit, the export was entirely stopped.

I am convinced that had it not been for the war, the progress of development in agriculture for the past three years would have been greater, and that the total export figures of agricultural produce would have been larger than those already quoted.

DISCUSSION.

The Chairman (Viscount Gladstone) said that he sympathised very heartily with the personal tribute to South Africa with which the author concluded his paper. The longer one lived in South Africa the fonder one became of it; it was a country of increasing fascination, and personally he always took a deep interest in everything that concerned it. The author had rightly said that South Africa was a loyal part of the British Empire. Especially at this time English people liked to remember that that was so; they knew now something of the immense sacrifices and heroisms of South Africa's sons on many a hard-fought field, and they felt it to be their duty to take an interest in all the details of the trade and commerce of South Africa, which were of the highest importance not only to that country but to the Mother Country as well. The author had described the number and variety of the trades and industries of South Africa, and probably many who did not know very much about the country would be surprised to hear how great and varied those trades and industries were. Many of them were as yet small in their development, but still

promised well for the future; others were doing very well at the present time, and not a few had attained quite large dimensions. Most people, when they thought about the industries of South Africa, thought at once of gold. It was true that gold was a very important industry in South Africa, supplying capital and revenue—both very useful things, especially in a new country—but it must be remembered that the production of gold had its disadvantages, in that it absorbed over 300,000 men, and therefore produced a shortage of labour which was essential to other industries. He had no doubt that the gold industry in South Africa would last for many generations, but if in the course of one or two generations it began to decline, he would not look upon that with any apprehension, because the labour would gradually be diverted to other industries which would be to South Africa of even greater value, and would tend to build up its economic future on greater and perhaps safer lines. With regard to exports from South Africa, they were not very large compared with those of older countries, but it must be remembered that South Africa did produce a great many commodities in the shape of raw materials which were greatly needed by this country and which, for some reason or other, other countries had been using a great deal more than we had. English manufacturers and business men must be made to realise the merits of South African goods, so that this country might not have the somewhat humiliating spectacle of raw materials being brought here and then sent off somewhere else to be made up into finished products—and not to a very desirable quarter. The subject of food was of even more importance to this country at the present time than that of raw materials; and, if we had been more alert in past years, South Africa would now be sending us more food than we were at present receiving from her. There was no limit to the possibilities of the development of food exports from South Africa; it was only a question of organisation and of using the vast spaces of the country. The railways, harbours and shipping were all ready, and if the industry was developed South Africa might become a great exporting country of meat, cereals, especially maize and wheat, sugar, and many other food substances. The fact that South Africa was now exporting about 2,000 tons of butter a year was of enormous potential importance to this country. South Africa required capital and labour, and he hoped the people who proposed to conscribe capital would be kind enough to leave a little for the development of South Africa, and that the various schemes put forward would be pared down by criticism and sound advice, so that the economic possibilities of South Africa would not be imperilled. Whatever was done for the promotion of its industries, there was no question of bolstering up those which were unsuitable for the country and costly and uneconomical. Experience had already shown that a great number of excellent industries had been started in South Africa on their own merits and were doing very well; whether or not they needed any further help he was not going to say at the present moment, but, at any rate, he was not afraid of any plans for their encouragement if those plans were clearly limited to vital industries, industries essential to the well-being not only of a particular part of the Empire but of the Empire as a whole. He had personal knowledge of the fact that the industries started in South Africa were started on excellent lines, were essentially economical, and were being built up on the soundest and best scientific principles; and when that condition of things prevailed he was not afraid of the plans of theorists and economists, with some of whom perhaps he did not agree. The author stated at the beginning of his paper that the constitution of the Union of South Africa gave freedom to all. That was quite true, and if one wished to develop the industries of a country one must see that the people of that country had full trust and confidence in the Government under which they had to live. South Africa was a difficult place with regard to politics; there was a good deal of exaggeration about them, and various questions arose very suddenly, and were apt to be forgotten almost as quickly as they arose. It was, however, one of the freest countries in the world, and by no ingenuity could any scheme of government give a freer life to the people who lived in South Africa. There were great onslaughts of political parties in that country, as there were in every country, and the past history of South Africa, perhaps, made people pay more attention to any signs of michief or danger; but for his part he was an optimist, and always had been an optimist, about South Africa, because in all the racket of South African politics no rational being had ever proposed to alter the Union, which gave security and the power of development to all its subjects. The Union of South Africa was a structure built of cement, reinforced by the knowledge that it was to everybody's interest to maintain it, and he believed that the structure which had been set up in the Act of Union would outlive all temporary difficulties that might arise. A hundred years hence it would still be flourishing, and so would its people—in manufactures, in agriculture, in exports, they would be taking a prominent place in the British Empire and in the world. The best return those present could make to the author for having brought the subject of the trade and commerce of South Africa so clearly before them would be to take to heart what he had said, and do all they could to develop that trade and commerce, for the benefit of South Africa and of the whole Empire.

Baron E. B. d'Erlanger said that, although he had never visited South Africa, he had for many years taken an interest in the development of the British Empire and particularly in that of South

Africa. With regard to the soap industry in South Africa, to which the author had referred, he had personally played a considerable part in the building up of that industry in the Transvaal, where it had been very successful. The Company was called the New Transvaal Chemical Company, but he might almost call it the United Trades of South Africa, because the industry was being developed in every possible direction. He was also a Director of the firm of Messrs. Pauling & Co., who had constructed about 40 per cent. of the 9,000 miles of railway that existed in South Africa, and of the British South Africa Company, which administered Rhodesia. He felt sure that sooner or later Rhodesia, as well as those colonies which we had just wrenched from German domination and oppression, would form part of the Union of South Africa. The possibilities of the industry and agriculture of Rhodesia were practically the same as those of the Union of South Africa. A country which was so well endowed with a natural wealth of soil, with gold, coal, iron, copper, asbestos and many other such metals, was one day sure to form the nucleus of one of the greatest industrial countries of the world. The British Empire had been developed and attained its present position on the keystone of commerce, industry and finance, concurrently with its Constitution, which had made its subjects so happy under its rule. If after the war, when its ravages had to be repaired, the British Empire was to continue its progress, the full development of all the resources of the Empire was absolutely necessary. If a capital tax was imposed in this country of such a magnitude as to cripple the financial potentiality of the country in after years, we should not be able to resume the development of the British Empire at the rate that was necessary to repair the ravages of the war, and he hoped the Government would take that fact into consideration.

Sir Charles H. T. Metcalfe, Bt., said that much of the progress of South African industries, to which the author had referred, was of very recent date. He could remember that four years ago eggs were imported into South Africa from Madeira and butter from New Zealand, whereas at the present time South Africa was exporting both of those products. There were also certain really important industries which were only in their infancy, such as the export of citrus oranges and lemons, which would arrive in this country at the time when they were most required—in June and July. He thought there was a very great future before that industry. The cotton industry was also only just beginning; he had been urging its development for very many years, and now it seemed to have really started. There was an enormous field for the development of the cattle trade; he had been through the statistics of farm after farm in Rhodesia, and found that the average increase of cattle, counting accidents, death, and so on, was sevenfold in five years. South Africa was very rich in base metals, which up to the present had not been worked to any extent. It took a long time to establish an industry of that kind, as could be seen by the history of the Tata works in India, and he has been trying since 1888 without success to start the establishment of iron-works in South Africa. He trusted, however, that he would live to see steel and iron works started by some broad-minded person in Africa, because the material was there in abundance, and the labour available was of the best variety.

Sir Edward Penton, K.B.E., in moving a vote of thanks to the author, said the paper showed that Mr. Chiappini possessed the gift of imagination, which Englishmen, sound as they were in commerce, frequently lacked. That imagination would have to be instilled into our trade development if we were to make full use of the produce of the Empire.

Mr. R. C. Hawkin, in seconding the resolution, said the paper was very opportune, for, after the Napoleonic wars, our Parliament voted £50,000 to encourage emigration from this country to South Africa, the reason for that being not so much that South Africa required the population as that the effect of the Napoleonic wars upon industry made some scheme of emigration absolutely essential to Great Britain. The organisation of that scheme was full of interest and importance to this country at the present time. There was no doubt that after the war there would be thousands of men who would be unwilling to return to their former employments, and would desire to emigrate to the Colonies. That was a state of affairs with which the Government of this country would have to deal, and he could not imagine any country more likely to attract those men than South Africa. There was a vast body of good unskilled labour in South Africa that required a certain amount of supervision; there were vast undeveloped resources; and there was a financial position in South Africa far stronger than in any other part of the British Empire. It was uncertain which of the various industries of South Africa would be taken up by the immigrants, but he thought the author was quite right in dealing with agriculture first. The tendency of the population in South Africa was to move from the towns into the country, and that movement would probably continue in increasing volume after the war. The fortunes to be made in agriculture in South Africa made even the gold industry seem unattractive. He saw no reason why the great coal resources in that country should not be developed. Coal was the main cause of England becoming a successful industrial country, and few people had any idea at present of the vastness of the coal deposits in South Africa.

The resolution was carried unanimously, and acknowledged by Mr. Chiappini.

Lord Harris, in conveying the thanks of the Society to Lord Gladstone for presiding, said that

all those present felt honoured by his attendance, not only on account of his personal distinction, but on account of the great name he bore. Turning to the subject of the paper, one of the chief things that South African agriculture required for its development was water. Agriculture was of great importance to any country, because it was the one industry by which one could gain something without any further expenditure of capital. Precisely the same amount of money was spent on a farm whether the year was a good or bad one, but in a good year twice as much produce might be obtained from the soil as in a bad year. That was purely due to nature, and agriculture was the one industry which produced without an extra amount of labour an increased amount of produce. South Africa was finding out the reasons for the animal pests which had been such a bar to her progress, and was now exporting agricultural produce. The author had not paid much attention in his paper to the subject of forestry, except with regard to wattle. Forestry was not a matter that could be arranged in a few years, or even in several decades; one had to look a very long way ahead to establish a great forest industry, but he was sure both the author and the Chairman would agree with him that South Africa was greatly in need of an increase in her forests. A company with which he was connected had been doing its best to enlarge the forest areas in South Africa, without receiving much encouragement from the Union. He thought the Union should give every encouragement to the planting of large areas with forests, because there was no doubt that an increase of the forest areas would tend to increase the rainfall, which was so much needed for agriculture.

THE CHAIRMAN, in returning thanks, said that the Union Government had done a considerable amount of work with regard to afforestation, and hundreds of thousands of acres had been planted with trees, but he quite agreed that the work might be done on a much larger scale. The question of water was, of course, a difficulty, and meant the expenditure of more money. He thought everyone who visited South Africa agreed that all the vast areas of land unsuitable for other cultivation should be planted with trees, and he hoped that in time that would be done.

The meeting then terminated,

OBITUARY.

LIEUT.-COLONEL CLIFFORD PROBYN, D.L.—Lieut.-Colonel Clifford Probyn died at his residence in Regent's Park on the 10th inst., at the age of seventy-six. He represented the Strand Division on the London County Council, of which he had been a member since 1889. He was Mayor of Westminster in 1901–2, and one of His Majesty's Lieutenants for the City of London. He had been a member of the Royal Society of Arts since 1876.

GENERAL NOTES.

INSTITUTION OF PETROLEUM TECHNOLOGISTS.—The possibility of producing from home sources, hitherto neglected, a certain proportion of the vast amount of mineral oil and its kindred products, now so vital a necessity to our national existence, has been much canvassed for some time past in both the general and technical press, and at the next meeting of the Institution of Petroleum Technologists on the 19th inst., at 8 p.m., at the Royal Society of Arts, a paper will be read, dealing with the subject, and entitled, "A New British Oil Industry," by E. H. Cunningham Craig, Dr. F. Mollwo Perkin, Mr. A. G. V. Berry, and Dr. A. E. Dunstan. The President of the Institution, Mr. Charles Greenway, will occupy the chair.

COTTON INDUSTRY IN KOREA.—A company has been formed for the purpose of erecting a mill and carrying on a cotton-spinning and weaving industry in Korea. The capital of the company is 5,000,000 yen. The mill will spin fine yarns and manufacture shirtings from Korean upland cotton. According to the *Eastern Engineer*, it is hoped that the enterprise will prove much more profitable than similar undertakings in Japan, because of the local supply of raw material and of the cheap labour available.

MEETINGS OF THE SOCIETY.

(*Up to Easter.*)

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 20.—MAURICE B. ADAMS, F.R.I.B.A., "Picturesque Architecture." JOHN SLATER, F.R.I.B.A., will preside.

FEBRUARY 27.—SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

MARCH 6.—A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 13.—PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The ARCHBISHOP OF CANTERBURY will preside.

MARCH 20. — FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m.:—

MARCH 14.—

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

MARCH 5. — GEORGE YOUNG, M.V.O., ex-Secretary of Legation, Lisbon, "Portugal as a Colonial Power."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." Three Lectures.

Syllabus.

LECTURE I.—FEBRUARY 18.—*The Economic Condition of the United Kingdom before the War.* Population—Migration—Occupation of population—National production—National consumption—National wealth—Agriculture—Shipping—Investment of capital abroad—Balance of trade—Position of the United Kingdom in international trade before the war—National debt—National finances—Federal finance — General character of trade policy before the war.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. E. Crammond, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture I.)

Victoria Institute, Central-buildings, Westminster, S.W., 4.30 p.m. Mr. E. W. Maunder, "Sunspots and some of their Peculiarities."

Engineers, Cleveland Institution of, Corporation-road, Middlesbrough, 7.30 p.m. Mr. G. M. Brown, "Rolling-mills and their Electrical Equipments."

Geographical Society, Kensington-gore, W., 5 p.m. Mr. E. A. Reeves, "A Transformation of the Magnetic Dip Chart."

TUESDAY, FEBRUARY 19...Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Messrs. E. H. C. Craig, Dr. F. Mollwo Perkin, A. G. F. Berry and Dr. A. E. Dunstan, "A New British Oil Industry."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Mr. G. Drage, "Statistics of Poland and Lithuania."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "The Problems of British Anthropology." (Lecture III.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. 1. Discussion on paper by the Hon. Sir Francis J. E. Spring and Mr. H. H. G. Mitchell, "The West Quay of Madras Harbour." 2. Mr. A. Meade, "Modern Developments in Gas-works Construction and Practice."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Professor E. W. MacBride, "The development of *Echinocardium cordatum.*" 2. Captain G. D. Hale Carpenter, "An African Civet attacking Human Beings." 3. Mr. L. A. Lantz, "Reptiles from the River Tajan."

WEDNESDAY, FEBRUARY 20...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. M. B. Adams, "Picturesque Architecture."

Aeronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Meteorological Society, 70, Victoria-street, S.W., 5 p.m. 1. Mr. F. A. Bellamy, "On the Barometer Record at the Radcliffe Observatory, Oxford, with special reference to Professor Turner's suggested discontinuities." 2. Dr. C. Chree, "The Diurnal Variation of Barometic Pressure at seven British Observatories, 1871-1882. A correction and some additions."

Geological Society, Burlington House, W., 8 p.m.

Electrical Engineers, Institution of (Local Section), University, Edmund-street, Birmingham, 7 p.m. Professor M. Maclean, "Kelvin as a Teacher."

Microscopical Society, 20, Hanover-square, W., 8 p.m. Professor B. Moore, "Photo-synthetic Action induced in Living Cells, and their Products." 2. Colonel Rawson, "Illustrations of Preparations."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Lieut.-Colonel L. W. Harrison, "The Management of Venereal Disease in the Civil Community."

THURSDAY, FEBRUARY 21...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. J. B. Gatenby, "Notes on the Bionomics, Embryology, and Anatomy of certain Hymenoptera Parasitica, with special reference to *Microgaster connexus*, Nees." 2. Mr. W. B. Brierley, "Experimental studies in the specific value of morphological characters in the Fungi."

Chemical Society, Burlington House, W., 8 p.m. Lecture by Professor R. H. Strutt.

Royal Institution, Albemarle-street, W., 3 p.m Dr. E. Gosse, "Three French Moralists, and their Influence on the War — La Bruyère." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. W. Sanderson, "The Dolomites and Austrian Tyrol."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 5.30 p.m. Dr. C. C. Garrard, "Switchgear Standardisation."

FRIDAY, FEBRUARY 22...Royal Institution, Albemarle-street, W., 5.30 p.m. Mr. A. Clutton-Brock, "The Importance of Art."

University of London, Slade School of Fine Art, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture VI.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

SATURDAY, FEBRUARY 23...Women Clerks and Secretaries, Association of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 3 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Problems in Atomic Structure." (Lecture II.)

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,405. VOL. LXVI.

FRIDAY, FEBRUARY 22, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, FEBRUARY 25th, at 4.30 p.m. (Cantor Lecture.) EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture II.)

WEDNESDAY, FEBRUARY 27th, at 4.30 p.m. (Ordinary Meeting.) SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, February 18th; Mr. JAMES SWINBURNE, F.R.S., in the chair. Mr. EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, delivered the first lecture of his course on "The Effect of the War on the Economic Condition of the United Kingdom."

The lectures will be published in the *Journal* during the summer recess.

ELEVENTH ORDINARY MEETING.

Wednesday afternoon, February 20th; Mr. JOHN SLATER, F.R.I.B.A., in the chair. A paper on "Picturesque Architecture" was read by Mr. MAURICE B. ADAMS, F.R.I.B.A.

The paper and discussion will be published in the *Journal* of March 15th.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s*. each, on application to the Secretary.

EXAMINATIONS.

The number of entries for the Examinations to be held in March is 10,712. Last year the number was 10,411.

PROCEEDINGS OF THE SOCIETY.

NINTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 6th, 1918; SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Bamber, Herbert Kelway, M.V.O., Datchet.
Campbell, Donald Fraser, London.
Galpin, Stanley M. A., Aylesbury.
Gell, John, M.I.E.E., London.
Gridley, Charles Oscar, London.
Hinchley, Professor John William, A.R.S.M., Wh.Sc., F.I.C., London.
Murdoch, J. Alfred, London.
Parkes, Samuel Thomas Hickling, Birmingham.

The following candidates were balloted for and duly elected Fellows of the Society:—

Balston, Reginald M., London.
Beamish, Richard H., D.L., Cork, Ireland.
Beckett, Joseph Edge, London.
Dawson, Charles Williamson, London.
Dewar, James M., London.
Dyson, Sir Charles Frederick, J.P., Windsor.
Jack, Henry Joseph, North Wales.
Livingstone-Learmonth, Thomas Livingstone, London.
Love, Charles William Grosse, London.
McKnight, William Archibald, Chile, South America.
Miller, Hans Eric, London.
Sowrey, Major John, R.F.C., Newmarket.
Woodward, William Harrison, Farnham, Surrey.

The paper read was—

THE DEVELOPMENT OF THE MINERAL RESOURCES OF THE BRITISH EMPIRE.

By WM. FRECHEVILLE, A.R.S.M., M.Inst.M.M., Professor of Mining at the Royal School of Mines.

In attempting to deal with such a wide subject in a single paper, it is evident that only outlines can be touched on here and there; but even so the attempt seems worth making at the present time, when everything is undergoing searching scrutiny to see in what directions we may with advantage alter or amend our ways.

In preparing the following notes, mineral resources—other than coal and iron—have been specially in the mind of the writer, as it is with them he is specially acquainted, but he believes the remarks and suggestions made will be found, in many cases, to be also applicable to coal and iron.

Some of the points discussed relate specially to home mining, and others to the overseas parts of the Empire; but they are taken as they arise, the subject being approached from the standpoint that the mining industry of the Empire forms one great whole, and that what will help one part will help the whole.

It is assumed that the importance of these mineral industries may be taken for granted. It is common knowledge that they have played a very important part in our industrial development in the past, and not only have the direct products of the mining industry contributed to this, but the population attracted by it has afforded a needed and welcome market for the produce of such agricultural or pastoral countries as Australia and South Africa.

We know how important a part metals and the metal industries are taking in the present war, which has brought into prominent light an aspect of the question that has been almost entirely overlooked in this country heretofore. It is now seen that the possession of sources of the metals required in the manufacture of munitions of war is of great national importance, and that when it is attempted to draw up a list of these it appears that in some way or other they are nearly all required. This national need of the metals in times like the present becomes so insistent that other considerations, including that of cost, have to be put on one side.

With regard to the future, it is a matter of common belief that metals and the metal industries, including that of metal mining, will play an important part after the war is over, and this belief appears to be well founded, for not only will there be the waste of war to be repaired and reinstated, but the world generally has been obliged to go short, for the period of the war, of a great variety of things into the construction of which these metals enter, and there will be this accumulated demand to be dealt with. Over and above this there is the further fact that we shall have great financial burdens to bear, in order to pay the interest, and it is to be hoped some amortization, of our huge War Loans, and the most obvious way to achieve this would seem to be to speed up our activities generally, so as to produce more, and amongst other things to produce more metals.

The question then arises, what means appear to be most likely to produce this result of increasing the production of metals, and the endeavour is made in the following to suggest some answers to this.

Production can evidently be increased either by increasing the output of known mines, or by the discovery and opening up of new mines, and anything which promises to do either of these things may be regarded as worthy of careful consideration.

Dealing first with increased production from known mines, the most obvious and quickest stimulus would no doubt be that their working should yield good profit, and as for any given supply of ore this depends on cost of production and price of product, anything that reduces cost or increases the price of the product will tend towards the desired result.

With regard to cost, the efficiency of labour plays a very important part, and probably most metal-mine managers would agree with the view that their workmen could, without hurting themselves, accomplish a good deal more than they do. There is a general feeling that the men, even when working on contract, do not let themselves go to the extent they might, the explanation being that they often fear that if they do more, and in consequence make a good thing out of their contract, the price would be "cut" or reduced for the next monthly contract, with the result that they would have to work harder for the same wage. There is the further fact that the present system does not seem to bring out any community of interest between the men and the mine, and we all know how much better results can, as a rule, be got by anyone who is interested in the result and works with

his head as well as with his hands. These difficulties exist no doubt in other industries, and in some, perhaps, to a greater extent than in the metal-mining industry, and they probably constitute the principal industrial problem awaiting solution in the after-war days, when we hope many of the difficulties and shortcomings we are now keenly conscious of, will be seriously dealt with. This problem is evidently a very difficult one to solve, or someone would have hit on a solution ere now, but it is a very pressing one. On the one side are the men holding back, and on the other side increased working costs, and opportunities of production not being utilised to the full. To the writer it seems that probably the key of the situation lies in the fact that the men who do the work are not, perhaps, obtaining their fair share of the wealth they produce and of the good things that are going. Starting from that proposition, it appears that it should not be beyond the bounds of human ingenuity to devise some way by which, in conceding higher wages, more strenuous and intelligent labour should be obtained. In doing this it may be there would be found sufficient margin to ensure that the cost of production did not increase, and in any case we should obtain increased production and all it implies. It seems likely that in any case there will be a permanent increase of wages all round, and it would seem wiser to face this and to use the opportunity for obtaining increased efficiency, rather than allow the present unsatisfactory state of affairs to continue. The evidence that is available in the metal-mining industry does not point to high wages being necessarily followed by high cost of production. The United States, with high wages, show working costs per ton that compare favourably with other countries with much lower wages. In different parts of our own Empire we see the same thing: for instance, the costs per ton at Kalgoorlie in Western Australia, with a ruling rate for miners' wages of 13*s.* 4*d.* per day, have compared favourably with parallel costs in Mysore, with the rate for native miners at 8*d.* per day or thereabouts, the result being obtained by the greater efficiency demanded and obtained from the more highly-paid man.

Another possible way of reducing working costs, and also of reducing waste, is in finding out and introducing improved methods, and the recently established Committee on Scientific and Industrial Research should have a fruitful sphere of usefulness ahead of it. Some might be inclined to argue that an inventor is born and not made, and that his achievements cannot be controlled; but although there is probably a good deal of truth in this as regards abstract discoveries, it does not apply to the same extent to the inventor who designs new appliances, or works out new applications of known laws. Granted that the inventor is a specially gifted man, there is no reason why his gifts should not be directed into certain promising channels, and if an increased scope for investigating and inventive gifts existed, we should probably find that they are not so rare as is sometimes supposed. The possibility of "an invention to order" seems to be certainly proved in the domain of industrial advance, or else why do some large firms, notably some large foreign chemical manufacturers, keep a staff of skilled experts working out improvements of method or apparatus? In mining, too, typical discoveries to order may be cited. There is the well-known case of the Davy safety lamp, invented by Sir Humphry Davy in response to an appeal to help the coal-miner, who had to work exposed to the dangers of explosive gases. The McArthur-Forrest gold extraction process may be quoted as another instance. A Glasgow company, called the Cassel Gold Extraction Company, was formed to acquire a gold extraction process, which unfortunately did not prove a success. A chemist working for this company, Mr. J. S. McArthur, and two brothers, Mr. Robert and Mr. Wm. Forrest, took up the research to see if they could find some solvent of gold that would answer, and Mr. McArthur has described how they tried one after another all the solvents of gold they could think of, or of which they could find mention, with the result that the cyanide process which bears their name was evolved.

The instances cited also give an idea of the importance industrial inventions or improvements may have. If it were possible to appraise the value of the discovery of the Davy lamp to the industry of this country, it would, no doubt, be found to be a very large figure. The same may be said of the cyanide process. The total gold production of the world is now close to a hundred million sterling—it is given as £96,000,000 for 1916—and the major part of this is mill-gold, that is, gold extracted from ore by crushing and subsequent treatment, in which the cyanide process plays its part. Previous to the introduction of this process, the total extraction from an ordinary gold ore, making use of all the refinements then known,

was about 82 per cent., the remaining 18 per cent. being lost in the tailings, whereas now, by the aid of cyanide, the extraction is about 92 per cent. of the contained gold.

It thus appears that in working in this field, the reward, from a national point of view, may be great, out of all proportion to the outlay.

Another direction in which much more assistance might with advantage be given to the metal-miner in England, is in the careful geological examination of the ground and the unravelling of such problems as might be useful to him. Geologists in this country for some reason have almost entirely ignored metal-mining. Whatever the reason may be, this attitude is surely a great mistake, and one which must have worked as a serious disadvantage both as regards progress of our knowledge of the geological side of mining, and also to the industry.

Speaking generally, the policy in this country in the past has been to leave nearly everything to private enterprise and endeavour. While not wishing to advocate what is sometimes called "spoon-feeding," and frankly acknowledging that in some directions the policy has been justified by the results, one cannot help raising the question whether we have not carried the practice of Government aloofness too far.

Take the case of the Cornish tin-mining industry. The price of tin is abnormally high just now, which has put the industry on a securer basis than it has occupied for a long time past, but one has only to travel over the county and see the remains of former mines and mining operations, to realise that the industry has been a decaying one. In fact, there have been periods during the last decade or two when it has appeared to be almost in danger of extinction. Beyond the direct loss which would be caused by the cessation of production, attention may be drawn to the important *rôle* Cornish miners and foremen have played in the development of metal-mining throughout the Empire, and one cannot but think that an effort to rehabilitate the industry is well worth making. It would have to be made on wise lines, however, or it would be likely to do more harm than good.

Metal mines in England are frequently carried on under the terms of a mineral lease, the usual terms of which are that the mine is taken from the landowner for a limited number of years, subject to the payment of a rent and certain royalties. It may be pointed out that a lease of this kind does not seem a particularly happy basis on which to carry on an industry like mining, requiring the expenditure of large sums of money in such things as plant, buildings and shafts, and, moreover, the insecurity of tenure must act as a severe hindrance, particularly towards the end of the term. It may further be pointed out that the rent or royalties have to be paid before those who risked their money in the mine can receive any dividends, and also that when, as is sometimes the case, the royalties are exacted from mines which are not paying, their incidence is severely felt. Development of the known ore-bodies and exploration or search for new ones are the very life-blood of metal-mining, and if they are neglected, all but the exceptionally rich mines will languish and fail. When a mine is in a non-paying condition it is doubly necessary that development and exploration should not be neglected, and when royalties are exacted under these conditions money is diverted that would otherwise be available for this purpose, and diverted at a time when it is very difficult for those working the mine to replace it. If the owner could only be got to see the matter in its proper light, it is really a short-sighted policy to exact royalties under these conditions, as the result of doing so may very likely be detrimental to his own interests.

Another direction in which those who work metal mines suffer is in the incidence of income tax. As is well known, a metal mine does not go on indefinitely, but as the ore is extracted it is not replaced, and sooner or later the mine is worked out or exhausted. The profits that are paid should, therefore, properly be regarded as partly interest on the investment and partly as return of capital. Income tax as now levied takes no cognisance of the fact that the mine is a wasting asset, and demands and takes its toll from the capital as it is returned, as well as from the interest. As long as the income tax was a shilling, or a little over, in the pound, the hardship did not press severely; but now that it has risen to five shillings in the pound it is distinctly a case for inquiry, and it is to be hoped that the application which is now being made to the Government by representatives of the industry concerned may result in an equitable adjustment.

From the above statements it will appear that while little assistance has been given to home metal-mining, it has in some respects been hardly treated, and although it is not contended that this alone is the sole cause of its present state of decadence, still it has, no

doubt, contributed to that result. The industry generally, it must in fairness be stated, has also to struggle against two great natural difficulties —increase of depth and falling off in value, but these, it may be pointed out, are not necessarily fatal maladies at any particular stage. The depth is not so great as that at which metal mining is successfully carried on in some other parts of the world, and as regards falling off in value, although this is an ill which is hard to fight when it comes with increasing depth, still ore-deposits notoriously vary from time to time, and there may well be, and probably are, in some cases rich bodies of ore awaiting the attack of the miner underneath or by the side of the present impoverished workings of some of the mines.

Having in the foregoing touched very briefly on certain difficulties and handicaps which at present are rather pressing on the home metal-mining industry, let us pass on to consider the possibilities for expansion in mining which undoubtedly exist, particularly in the overseas parts of the Empire. Looking at the Empire as a vast estate, large parts of which still await exploration and development, the first and obvious step would appear to be to find out what we have. While encouraging exploration and prospecting by others, it is suggested the estate owner should himself take some active steps in the matter, and, by means of the examination of the country by skilled men, ascertain the importance of known mineral discoveries, the most likely ground for prospecting, and generally the wisest policy to pursue to encourage the mining industry for the good of the community. In our Crown Colonies this should be done under the control of the Home Government. In other parts of the overseas Empire the Governments of the great Dominions already give much attention to the development of their mineral resources, but the territories they administer are so huge there is ample scope for doing more if the means were available.

An Imperial Mineral Resources Bureau is, it is understood, now being formed, and to aid in the above developments would appear to be one of the many useful and important functions that a wisely constituted bureau might perform.

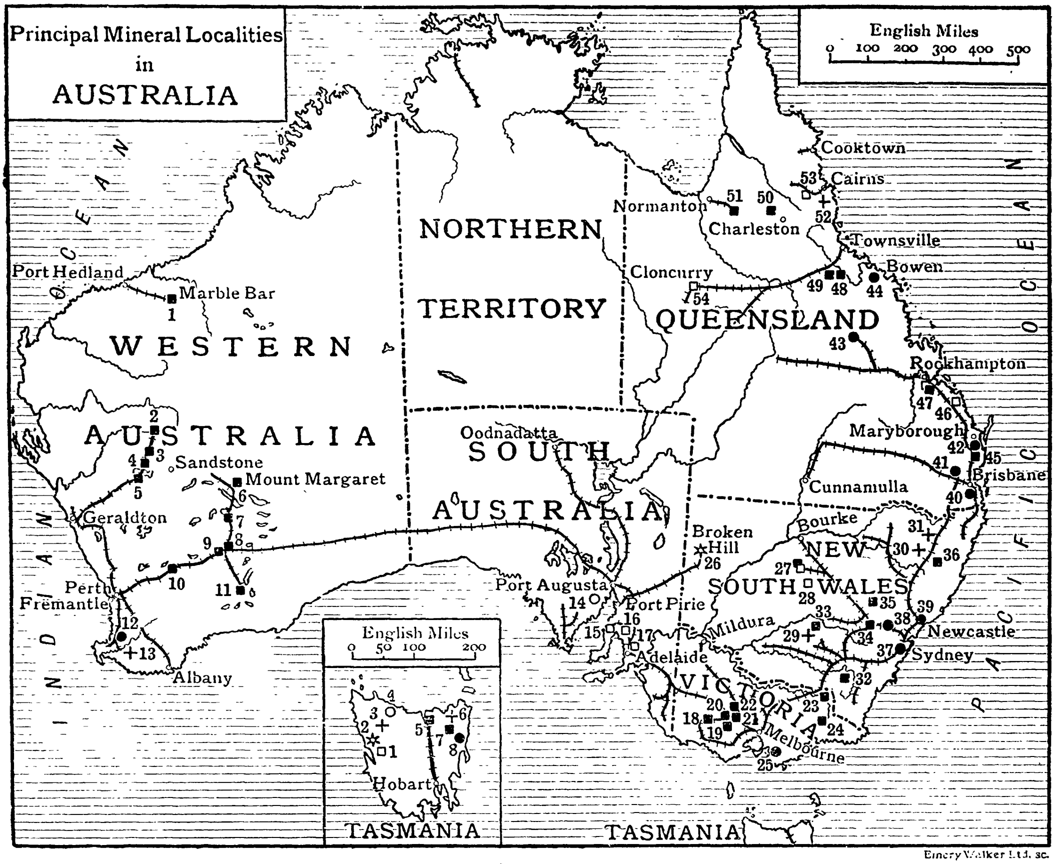
It is to be hoped this bureau when established will be on a thoroughly wide and comprehensive basis, and that the great Colonies will be adequately represented.

It is not possible within the limits of this paper to illustrate as fully as it deserves the contention that there is great scope for expansion in the overseas parts of the Empire, but in the short time at our disposal three instances may be mentioned, and these will be taken from Ceylon, a Crown Colony, and Australia and Canada, great self-administering Dominions.

Ceylon, as is well known, produces a considerable part of the plumbago or blacklead consumed by the world in the manufacture of crucibles for the metal industries, and for other useful purposes. The industry is quite an important one, as in the pre-war years the annual export of plumbago from Ceylon was valued at about half a million sterling, and constitutes about one-third of the total production of the world. In spite of its importance, however, it is rather humiliating to note that no adequate geological study of the occurrence of plumbago in Ceylon, or technical study of the methods of mining and preparation, appears to have been made. This is certainly not in line with the methods that are adopted in other countries which take a closer interest in the development of their mineral resources. It is suggested that the whole subject—geological and technical—should be carefully studied by competent men and described in a monograph, and compared with plumbago occurrences and methods of working elsewhere. In this the industry concerned might gain valuable information, and outside people would have an opportunity of judging as to what opening there may be there for their enterprise or special knowledge.

The plumbago industry in Ceylon appears to be carried on entirely by natives, and, from what one can learn, in a very primitive way. A similar state of affairs used to exist in the tin-mining industry in the Straits Settlements, where of late years considerable advantage has been gained in the direction of working poor deposits by improved methods and machinery.

With regard to Australia, the second instance cited, attention is directed to the map on page 250, which illustrates the distribution of the principal known mining centres in that great island continent. Commencing with Western Australia on the one side, and passing round by South Australia, Victoria, New South Wales, and Queensland, it is seen that the known mining centres, which are indicated on the map by a dot, all follow round the coastlands up to, say, from three to four hundred miles inland; that is to say, they are in the strip or zone of country that has



Gold ■ *Copper* □ *Silver-Lead* ✲ *Tin* + *Iron* ○ *Coal* ◉

been travelled over and prospected. Beyond this there stretches a very little known interior, with no mines working and no dots on the map. Looking at this diagram broadly, and taking into consideration the plentiful way in which the dots are sprinkled over the country near the coast, and how they are absent in the interior and in the little known Northern Territories, one cannot avoid the conclusion that the absence of mines in these parts is not so much due to the absence of mineral wealth as to the fact that the country is still largely unprospected.

The same reasoning may be applied to Canada, the mining centres of which are shown on page 251. In this case the producing mineral districts are seen to follow the railways in a curiously persistent way; in the first instance the great east and west transcontinental railways, and then the north and south branches. In Australia the mineral discoveries have been made first, and then railways have been constructed to connect them with the coast, but in Canada, as a rule, the railways have been built first and then mineral discoveries have been made either on the line of railway or not far off. The explanation of this lies in the climatic history of the two countries. In Australia the fragments of ore which break off from where the valuable mineral "crops out," or comes to the surface—which is called "float" by the miner—lies about and is not difficult for the prospector to find, whereas in most parts of Canada the surface has been planed off by the great glacial sheet which at one time covered the land, and the chips or fragments that have been planed off have been ground to powder by the movement of the ice-sheet, and carried away and distributed perhaps hundreds of miles from their source. In consequence of this the "float" is not there to aid the prospector, and the normal condition is that under a few inches or a few feet of moss or glacial clay the smooth ice-worn unweathered rock is found, and if there are mineral veins or deposits in it they are hidden by the moss or soil, and do not actually appear on the surface. This makes prospecting more

difficult in Canada than it is in countries which have not been glaciated or ice-worn, and it also accounts for the fact that, until comparatively recently, Canada seemed to be behind other parts of the Empire in mineral wealth.

A general examination of the diagram of the principal mining centres of Canada will lead to very much the same conclusion as was indicated in the case of Australia. The mining centres are scattered through the known and prospected belt of country stretching from east to west, and the fact that they are absent in the little known and almost quite unprospected great northern country is in all probability not due to their non-existence, but to their not having yet been found.

In one part of this little-known northern part of Canada there is already evidence of the existence of copper over a large area. Specimens or nuggets of native copper were first obtained from the Esquimaux, who used the metal for their implements, and the occurrence was subsequently confirmed by the few travellers who have been in that region; and it is interesting and significant to note that the specimens of rock which have been brought from these, point to the occurrence being geologically similar to that of the highly productive and profitable copper-mines of the Lake Superior district of the United States.

The new copper district referred to is situated east of Great Bear Lake and along the course of the Copper Mine River, which runs north from about Lat. 65° into Coronation Gulf in the Arctic Ocean. Evidences of the occurrences of copper are also reported as far east as Bathurst Inlet, and on Victoria Island. Amongst others, the Canadian traveller and geologist, J. B. Tyrrell, has drawn attention to this possible copper-field, and the broad facts as stated may be taken as established. The present position may be summed up by saying that there may be a great copper-field somewhere in that region awaiting development, and that the locality is worthy of being carefully examined and prospected both from a Canadian and from an Imperial point of view. Its rigorous climate, remote position, and the difficulty of access, have hitherto stood in the way of this being done. It would require a summer to go, another summer to make a preliminary examination, and a summer to return — say two and a half years in all to make even a preliminary survey. Even so, the economic and national importance of a great copper district would seem amply to justify the effort.

It may be mentioned that Arctic conditions are no bar to successful mining operations, as the mines of the Klondike are in Lat. 63° to 65°, and the Sulitelma copper-mines in Northern Norway, and the Gellivare iron-mines in Swedish Lapland, are both within the Arctic Circle.

With regard to access for examination, in view of what is taking place around us, it does not require much, if any, expansion of what has already been done, to allow aeroplanes to be considered as a possible help, particularly in view of the fact that the numerous lakes in that region would appear to facilitate the establishment of landing and supply stations.

One of the features of the times through which we are passing has been the high prices commanded by the various metals when free of Government control. The metal, copper, for instance, commands now a price of about £110 a ton, against about £60 in ordinary times, and no doubt the purchases of the large requirements of the Government have to be made at somewhere about the higher figure. Perhaps we shall learn the exact figures relating to these purchases some day, and it would not be surprising if perhaps the excess profits—that is the extra profit due to war conditions—made by the American copper producers on one deal alone would suffice, or more than suffice, to construct a railway such as would be required to open up the part of Canada referred to, remote as it is.

The obvious objection to the suggestion that Governments might, with advantage, adopt a more active policy in developing their mineral resources, would be on the score of expense. Two answers to this suggest themselves—one being that the expansion of the mineral industry would be of great benefit to the country and Empire, and the other that in cases where Government aid had been given, and public funds expended, it might seem only fair that the Government or Governments should participate in some form in the result, if successful. One solution of the problem how this may be done is being worked out by the South African Government in connection with the Far Eastern Rand Gold Mining Areas, which are now, from time to time, being put up to public tender. The basis on which the tenders are made is that a share of the profits, calculated on a sliding scale, has to be paid to the Government, and the one who offers the greatest share obtains a lease of the ground for the life of the mine,

subject to the conditions of the lease being fulfilled. The system appears to be a fair one, and to be working well.

In the foregoing the writer has made suggestions here and there of action which, it appears to him, would aid the development of our mineral resources, and has quoted cases which illustrate the views he has in mind. No attempt has been made to cover the ground, but the writer hopes enough has been said to establish the soundness of the view that a good deal might well be attempted in several directions, with a reasonable assurance that the results would justify the attempt.

DISCUSSION.

THE CHAIRMAN (Sir Dugald Clerk, K.B.E., D.Sc., F.R.S.), in opening the discussion, said it was of vital importance to the British Empire that the population of its Colonies should be much increased. At the present time the population of the British Isles was about 46,000,000, whereas there were only 16,000,000 people, excluding the native inhabitants, in the whole of the rest of the Empire, including Canada and Australia. The population did not rapidly increase in a purely agricultural country, but it did so in an industrial country; and it was greatly to be desired that both Canada and Australia should become important industrial countries. That could be brought about—given a sufficiently liberal policy on the part of the Governments and on the part of the people themselves—partly by means of mining and partly by an increased use of the water powers of the countries, particularly in Canada. It was a fascinating possibility that in the districts with which the author dealt, not only could minerals be obtained, but also the water power to work them, and possibly also the water power and mechanism for working them up into finished products by the electrolytic and the electro-chemical processes so much in vogue at the present time. It was necessary, as the late Professor Seeley said in his "Expansion of England," to have at least 50,000,000 people of our own race in the parts of the Empire outside the British Isles, in order to secure the greater stability of the Empire.

MR. OCTAVIUS C. BEALE said he was glad to hear the author's remarks on the immense possibilities of Canada and Australia, and also the hint he threw out that the mining industry of the British Empire formed one great whole, and that what would help one part would help the whole. The difficulty of getting the whole mining industry of the Empire represented in London would be very great; but, at any rate, the separate portions of that industry might be represented in London by an authoritative body, which could deal with their respective interests. There should be a Zinc Committee, a Copper Committee, and so forth, to embrace the whole of what was not only an important part of our industrial development and of great national importance, but was absolutely basic. The people of this country had to decide now whether they were going to let Germany resume her former position after the war, and keep a control over the metals of the British Empire. Australia produced 450,000 tons of zinc ores per annum, and before the war the whole of that went for refining to Germany, with the exception of about 20,000 tons, and the German vessels which conveyed the ores took out the necessary machinery for working the mines. Germany had acquired an enormous amount of control over the metals of Australia and Canada, and now that this country was going to alter that state of affairs it was essential, not so much that there should be a great increase of the European population in the Dominions, as that that increase should be of the British population only. He had been asked in America whether it would not be better for Australia if she had a very much larger population; but his answer was that Australasia produced as much gold as the whole of the United States, and that her 6,000,000 people who owned that gold were better off than the 100,000,000 people of the United States. Again, Australasia had 110,000,000 sheep for her 6,000,000 people, whereas the United States had only 50,000,000 sheep for her 100,000,000 people. Why should Australia introduce a number of immigrants, who would perhaps lower the standard of living and reduce the rates of wages, rather than go on producing, as she did produce, all the steel and zinc and the great bulk of the copper that the British Empire required, if only there were wisdom enough in the United Kingdom to see that those metals came to British people? They should be given first to the British Empire, and secondly to the Allies, and then the neutral and enemy countries might take the remainder.

SIR WILLIAM GREY WILSON, K.C.M.G., said that the difficulty of the income tax in connection with metal mines, to which the author had referred, could and should be remedied by the directors paying a considerable amount of the earnings of their companies into the reserve fund, instead of distributing it as income. Although it was very difficult for a man to set aside half his dividend and treat it as capital, he thought it would be a very useful thing to do in the case of metal-mining companies. With regard to the question of Government aloofness, he did not think anyone connected with any company could accuse the Government of that aloofness since the war broke out. The Treasury had exercised the most drastic supervision over every company that had been started, and he believed that control had been most satisfactory, and should be continued after the war to a certain extent. It would, of course, be impossible for the Government to declare that an

venture was absolutely sound; but it would be quite possible for the Government to put a stop to the wild-cat schemes that were sometimes floated, and that did so much injury to the genuine development of the mining industry, by saying that they were not companies with regard to which they could sanction the issue of capital. In that way the general public could be encouraged to invest their money in mining industries, which had at times been under a cloud.

MR. E. H. CUNNINGHAM CRAIG said it was well known that there was a certain number of petroleum fields in the British Empire, and it was also well known by those who were interested in them that their development had been rather unfortunate. In some places there had been a great delay in regulating them, and in other places there had been a great delay in getting them into working order. The colony of Trinidad, for instance, had a very promising oilfield, but it had taken years to get it into such a condition that the ordinary shareholder could reasonably expect to obtain dividends from the various companies. The reason for that was that there had not been enough British control nor enough Government control. He had been told that at one time the two great oil corporations of the world met in order to divide the world between them, to mark out their spheres of influence so that one should not interfere with the other. One of those corporations was controlled by the Dutch and the other by the Americans, and they were both interested to some extent, through subsidiary companies, in Trinidad. He did not know if they ever decided what should be done with Trinidad, but he thought they both determined that if they did not work the oilfields of Trinidad themselves they would make it as difficult as possible for anyone else to do so. The result was that the development of those oilfields had been kept back for many years, and he thought that was a very good instance to show the necessity of having entirely British control of British Empire resources.

PROFESSOR C. GILBERT CULLIS said the author had rightly pointed out that if the British Empire was to increase its output of minerals it must adopt one of two courses—it must either make better use of known deposits, or discover or acquire fresh deposits. With regard to the better utilisation of known deposits, he would like to call attention to the extraordinary extent to which raw materials, or partially smelted materials, of British origin were at the present time, and had been for the past few years, exported from British territory to foreign countries for the production of the finished metal or of the manufactured article. For instance, Quebec possessed the finest deposits of asbestos in the world, but only a very small proportion of those deposits was worked up into the finished asbestos article within the British Empire, most of the material being sent to the United States for that purpose. Again, only a small proportion of the diamonds obtained from the South African mines were actually cut and made into finished stones within the British Empire; and a still more notorious instance was that of the zinc concentrates of Broken Hill. Before the war, some 500,000 tons of these concentrates were produced annually, of which only a few thousand tons were smelted in Australia and about 20,000 tons in England, the whole of the remainder going to Germany and Belgium for the extraction of the zinc metal. Nearly all the copper and nickel deposits of Ontario were sent to the United States for the extraction of the metals. That export of raw materials had two disadvantages. In the first place, the benefits in wages, in skilled labour, and in increased profits which attended the working up of a finished metal from an ore were lost to the British community; and, in the second place, the control of the finished metal or manufactured article, and the art of producing it, which was equally important, passed into alien hands. Our aim in the future should be to ensure that all British raw materials were treated within the British Empire, the finished products being exported rather than the raw materials. With regard to the discovery of fresh deposits, if such a discovery was to be made within the next few years, both the home Geological Surveys and and the colonial Geological Surveys must be greatly speeded up. Their staffs must be augmented, and those staffs must be composed to a certain extent of men who, besides having been thoroughly trained in the fundamental principles of geology, had also a sound knowledge of mathematics and a working knowledge of metallurgy. The results obtained would then, from the point of view of practical geology and the production of minerals, be very much better than they had been in the past.

MR. C. H. B. BURLTON said he would go a step further than the previous speaker, and not only confine the utilisation of the raw materials produced in the Empire to the various countries within the Empire but to the actual country in which they were produced. Unless the Government of a Dependency provided manufacturing industries therein, exportation to other countries would, as at present, be inevitable. He had been very much struck by the great disparity of wages that prevailed in different parts of the world, as indicated by the author. Miners' wages in Western Australia were given as 13*s*. 4*d*. a day and in Mysore at about 8*d*. a day, but he understood from the paper that the efficiency was fairly proportionate to the wages. He thought that if an Indian labourer turned out work to the value of 13*s*. 4*d*. a day and received that amount for it, he would think he had quite sufficient money to last him for a week, and very likely would not do any more work for the rest of the week. The remarks made in the paper with reference to the plumbago industry in Ceylon were very interesting. The industry in Ceylon was an important one, because it comprised about a third of the world's output of plumbago, and it was

certainly not very creditable to the Government of Ceylon, or whoever was responsible for the matter, that there was not more geological interest taken in the resources of that island especially with regard to plumbago. The mineral resources of India had been largely left to private enterprise, the Government granting a concession and then leaving the concessionnaire to sink or swim. That was not as it should be, and it was also inconsistent with what the author had said about expanding the mineral industry with a view to benefiting the countries from which the minerals were derived. India was very badly off for fire-bricks, but her mineral resources were such as to justify the erection of very large kilns for the calcination of fire-bricks by the Government. If such kilns were erected, not only would the Government be supporting the industries already in existence, but other industries would be created and there would be an enormous demand for fire-bricks, and all the manganese which at present went out of India would be utilised in that country. The iron ore would also be used, and there would be ironworks erected all over the country to utilise the materials derived from the mines in India.

Professor Frecheville, in reply, said that the difficulty in trying to develop the resources of Canada in the country of their origin, was that Canada was next door to the United States. The mining people in the United States were watching very closely everything that was found in Canada; they had plenty of money and plenty of enterprise, and unless steps were taken to prevent them doing so, they would probably get control of all the different deposits in Canada as they were discovered. A very large copper mine had recently been discovered in Manitoba, which had been proved to contain about six or eight million tons of ore of a low grade, but still profitable if worked on the huge scale on which the Americans worked their copper mines. £1,000,000 was required to work that mine, £500,000 for the railway and £500,000 for the plant. The people of Canada could not provide that money, and probably people in Great Britain would not care to do it, and the only people who really understood the working of those huge copper deposits were the Americans. The Government was being asked to do a great deal, and if they rose to the occasion they might do it, in which case they would pay themselves for it, and there was no reason why they should not. For instance, the South African Government was now offering mining areas on the Far Eastern Rand to tender; anyone could tender for them, and the ground was given to the man who offered the largest amount, the Government taking a share of the profits on a sliding-scale. He did not see why other parts of the Empire should not adopt the same system.

The Chairman then proposed a vote of thanks to the author for his interesting paper. An important fact to be borne in mind was that it was easier to obtain money for a gold proposition than for any other kind of mining. The total production of gold in the world was only £100,000,000 per year, which did not amount to one-twentieth of the income of Great Britain itself in one year. Gold was a very small part of the wealth of the world, and Canada and Australia should attach more importance to population and less to gold and minerals. The real wealth of the world depended on population alone, and as long as Canada and Australia had such small populations they would remain as poor as they were at present. Great Britain had the largest income per head of its population of any country in the world, with the exception of the United States.

The vote of thanks was carried unanimously and the meeting terminated.

Mr. Hugh Pearson writes:—The Chairman at the meeting on the 6th inst. accurately defined Professor Frecheville's paper when he said it was a suggestive contribution to a great subject, and it was a pity that time did not permit the Professor to develop his points thoroughly, and for a more complete discussion afterwards. As it is, he has given a lead, yet I cannot help thinking that a less comprehensive title would have been more in keeping with the scope of the paper. To exclude coal, iron, and petroleum from a discussion of the mineral resources of the Empire is to neglect three of the greatest necessities of the present age. It is to the first two that we owe, in a large measure, our greatness in the past. No country without motive power can become truly great, and something of this kind was evidently in the Chairman's mind when he referred to the possibilities of the water-power resources of Canada. And Germany recognised the value of iron in her determination to hold the stolen provinces of France. Unlimited cheap supplies of iron ore are the very life-blood of the nation. As for the third—petroleum—who would set limits to its possibilities? Our present strong position in the war has only been possible because of this great gift of nature. And in view of this fact I am not surprised that Mr. Cunningham Craig voiced his disappointment at no mention being made of its presence in the Empire, and no suggestion being given for the more active search for, and development of, known resources. It is true Mr. Frecheville said that the aeroplane might solve some difficult transport questions as he passed his pointer over the map of Canada from British Columbia to the Arctic Ocean, where, he said, deposits of copper ore exist. This is no fantastic suggestion. The progress of aeronautics during the war is convincing evidence that the future will see wonderful developments in this direction, but Mr. Frecheville lost a point to emphasise an argument when he failed to mention that in the intervening space traversed by his pointer there are large areas impregnated with desiccated petroleum, which some authorities believe will yet prove a mask to the presence of

valuable deposits of petroleum; and should this be realised, Mr. Frecheville's aerial transport order would find supplies *en route*, and probably a source of wealth infinitely greater than the original object of flight. It is to be hoped so at any rate, because, as it is, our position as producers of petroleum is not flattering to our national vanity. The Germans make rings round us all the time, and we generally realise the fact when it is too late. Take the Baghdad railway. We are told that it was being pushed eastward to increase German influence, and ultimately enable them to take our place in the East. This undoubtedly is true, but was there not another and a more immediately profitable object in view? Germans were amongst the first to explore the ruined cities of the ancient world, and claimed a good deal of credit for disinterested antiquarian research, but the fact is they scented oil, and have long been conscious of the petroleum possibilities of Mesopotamia, and had the war only been delayed a little longer, we should once more have found out how deep-laid and cunning were the schemes of our enemies. The action of the Government in stepping in to help the Anglo-Persian Oil Company was a bitter blow to them, and now that something of the facts are known, the public should be less hostile to the Government enterprise and keep their eyes on Mesopotamia. In conclusion, I wish to say that I heartily endorse all that Professor Frecheville said, and had space not been so valuable, I would have given some personal examples of my experience in further proof of his conclusions.

Professor Frecheville writes:—I have read Mr. Hugh Pearson's remarks, and quite agree with the views he expresses. I confined myself, for the time at my disposal, to the aspects of the question with which I am personally familiar, but fully admit that the consideration and discussion of the general lines that should guide us in developing our resources in coal, iron, and petroleum, would be very useful at the present time.

CORRESPONDENCE.

THE TATA IRON AND STEEL WORKS.

In the course of his paper on the above subject, published in the *Journal* of February 1st, Mr. H. M. Surtees Tuckwell gives the capacity of the Tata Works, and further on in the paper states that "the tonnage of pig-iron and steel corresponded approximately to that of the Frodingham Iron and Steel Company of this country."

As our outputs both of iron and of steel are very considerably larger than the figures given by Mr. Tuckwell, we shall be greatly obliged if you will correct this statement in your next issue.

Frodingham Iron and Steel Co., Ltd.

With reference to a letter from the Secretary of the Frodingham Iron and Steel Co., Ltd., taking exception to a comparison between the Tata Iron and Steel Works in India and the Frodingham Iron and Steel Company in this country, it would appear that the Secretary of the latter company has misunderstood the meaning which it was intended should be conveyed in the paper read before the Royal Society of Arts.

In this paper it is remarked that considerable enlargement had been decided upon, and that tonnage of pig-iron and steel consequent upon such enlargement corresponded approximately to the Skinnigrove and Frodingham Iron and Steel Companies of this country.

The contemplated outputs which the writer had in mind when making the above statement have been considerably expanded in the meantime, and when the extensions are completed, an output of 665,000 tons of pig-iron, 14,000 tons of ferro-manganese, and 656,000 tons of ingot steel are intended to be manufactured yearly.

It is much regretted if any annoyance has been caused to the Frodingham Iron and Steel Co., Ltd., and we trust that the above explanation will be entirely satisfactory to them.

Tata, Ltd.

OBITUARY.

The Hon. Rowland Gibson Hazard.—Information has been received of the death of the Hon. Rowland Gibson Hazard, which took place at Santa Barbara, California, on January 23rd. He was born at Philadelphia in 1855. After graduating in Arts at the Brown University (of which he subsequently was a Fellow) he went into business. In 1888 he became Vice-President of the Solvay Process Company; in 1890, President of Semet-Solvay Company; and in 1898, President of the Peace Dale Manufacturing Company. He was also a member of the Providence Harbour Improvement Committee. In addition to his business activities, he took a deep interest in various charitable and scientific institutions. He was a trustee of the Rhode Island State Sanatorium for Consumptives, and a member of the Linnean Society (New York), the National Association for the Study and Prevention of Tuberculosis, the American Forestry Association, the Franklin Institute, the American Ornithologists' Union, and other bodies. He joined the Royal Society of Arts in 1910, and took a very friendly interest in its welfare. From the outbreak of the war his sympathies were very strongly pro-Ally, and he devoted himself to propaganda work among his countrymen.

GENERAL NOTES.

Röntgen Society.—At a meeting of the Röntgen Society, held on February 5th, Mr. Batten read a paper on a simple means of obtaining "Static Currents" from an induction coil. The method consists in connecting one secondary pole of the coil to earth, whilst the other is connected

through a series spark-cap, oscilloscope tube, and a series condenser to the patient, who is placed on an insulated stand. The function of the condenser would appear to be that of a high resistance. The advantages of the apparatus are twofold. In the first place, it overcomes the troubles due to a wet climate, from which the static machine always suffers, and, secondly, it affords an inexpensive means, to those already possessing an induction coil, of obtaining currents similar to those produced by static machines.—Mr. E. E. Burnside read a paper describing a new mobile Snook apparatus. This is constructed on the same principle as the larger pattern hitherto in use, but is made in a more compact form by reducing the maximum spark-gap to 7 in.—Mr. Burnside also showed a small transformer constructed for employing the continuous current main supply to heat the spiral of the Coolidge tube. A small rotary converter changes the direct current into alternating current, which is stepped down to 12 volts by the static transformer: the secondary is well insulated from the rest of the apparatus, and regulation of the filament current is obtained by a variable choke-coil in the primary circuit of the transformer.

SEA-LEOPARD, WEDDELL-SEAL, AND PENGUIN OILS.—In a report presented to the Imperial Institute Committee for Australia on the recent work of the Institute for the Commonwealth, particulars are given of the results of an investigation into a series of oils prepared during the Australasian Antarctic Expedition and forwarded to the Institute by Sir Douglas Mawson. These materials included sea-leopard oil, Weddell-seal oil, and penguin oil. They have been carefully examined in the Scientific and Technical Department of the Imperial Institute, in order to determine their characters in comparison with commercial oils of a similar kind, and have also been submitted to buyers of such oils in the United Kingdom. The oils were of good quality, and could be utilised for the purposes to which commercial seal and whale oils are applied, viz., for soap-making, leather-dressing, burning, etc. There is no doubt that there would be a ready sale for consignments of any of these oils at about the current price of whale and seal oils if they should become availabe in commercial quantities.

WAX FROM SUGAR-CANE.—Wax, for some time past, has formed one of the by-products of the sugar industry in Natal, and its manufacture, according to the *South Africa Journal of Industries*, is now making very active progress. The process (which is patented) is somewhat intricate, but the treatment applied to an otherwise waste product (filter press cake from the sugar factories) results in the production of a very fine, hard, vegetable wax practically equal in value to Carnauba and beeswax, with which latter it is, chemically, almost identical. The wax has a high melting-point and takes a very high polish. After the extraction of the wax the large residue forms a fertiliser which is used entirely by the sugar estates forwarding their filter press cake for treatment. A refining plant has been equipped for treating crude wax for export, and for supplying an apparently general demand by manufacturers of furniture and boot polishes in the Union. About 250 tons of this wax have been shipped to London during the past two years, and the demand appears to be unlimited.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

FEBRUARY 27.—SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence), "The Organisation of Commercial Intelligence." The RIGHT HON. LORD FARINGDON will preside.

MARCH 6.—A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 13.—PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The ARCHBISHOP OF CANTERBURY will preside.

MARCH 20.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

APRIL 10.—W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "The Cotton Industry."

APRIL 17.—PERCY SHUTTLEWOOD, Ministry of Food, "The Food Situation in Germany."

APRIL 24.—MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War."

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry."

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 14. — WILLIAM FOSTER, C.I.E., "English Commerce with India, 1608–1658."

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoons, at 4.30 p.m.:—

MARCH 5. — GEORGE YOUNG, M.V.O., ex-Secretary of Legation, Lisbon, "Portugal as a Colonial Power."

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." Three Lectures.

Syllabus.

LECTURE II. — FEBRUARY 25. — *The Economic Condition of the United Kingdom after Three Years of War.* Transformation from peace production to war production—Position of women in commerce and industry—National production—National consumption—Inflation of currency—Rise in the cost of living—Rise in the prices of raw materials—Government control of labour, commerce, agriculture, shipping, etc.

LECTURE III.—MARCH 4.—*The Real Cost of the War and the Problem of Economic Reconstruction.* War expenditure of the British Government —War debt — Pensions — Education — Imperial Revenue and expenditure — Excess profits duty —Levy on capital—National debt after the war —Economic reconstruction — Problems of demobilisation—Commercial relations of the United Kingdom with the Empire and our Allies—Interaction of International trade and finance on the economic life of the United Kingdom — The investment of capital abroad.

J. YOUNG, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, FEBRUARY 25...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. E. Crammond, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture II.)

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m. Captain D. Bowen, "The Effect of Taxation on the Development of Mineral Estates."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Le Comte Renauld de Briey, "A Recent Visit in East Africa."

TUESDAY, FEBRUARY 26...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Lieut.-Commander H. T. Harrison, "A Survey of Methods of Directing and Concentrating Light."

Royal Institution, Albemarle-street, W., 3 p.m. Sir Richard T. Glazebrook, "A National Laboratory of Industrial Research." (Lecture I.)

WEDNESDAY, FEBRUARY 27...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Sir William Clark, "The Organisation of Commercial Intelligence."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Lady Barrett, "The Rôle of Midwife in relation to the Nation's Health."

Literature, Royal Society of, 2, Bloomsbury-square, W.C., 5.15 p.m. Professor M. A. Gerothwohl, "A Great Spanish Humorist (Armando Palacio Valdés)."

THURSDAY, FEBRUARY 28...Royal Society, Burlington House, W., 4.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Dr. E. Gosse, "Three French Moralists and their Influence on the War — Vauvenargues." (Lecture III.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Dr. G. H. Rodman, "The Domestic Fly—its Habits, Structure, and Menace to Health."

Britain and India Association, 33, Regent's Park-road, N.W., 4 p.m. Mr. H. S. L. Polak, "India Aspirant."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. C. F. Marsh, "Criticisms of the London County Council Regulations relating to Reinforced Concrete."

FRIDAY, MARCH 1...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor A. G. Green, "The Modern Dye Stuff Industry."

University of London, Slade School of Fine Art, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture VII.)

SATURDAY, MARCH 2...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Problems in Atomic Structure." (Lecture III.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—February 22, 1918.

No. 3406. MARCH 1, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,406. VOL. LXVI.

FRIDAY, MARCH 1, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, MARCH 4th, at 4.30 p.m. (Cantor Lecture.) EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture III.) HARTLEY WITHERS, Editor of the *Economist*, will preside.

TUESDAY, MARCH 5th, at 4.30 p.m. (Colonial Section.) GEORGE YOUNG, M.V.O., ex-Secretary of Legation, Lisbon, "Portugal as a Colonial Power." SIR OWEN PHILIPPS, K.C.M.G., M.P., will preside.

WEDNESDAY, MARCH 6th, at 4.30 p.m. (Ordinary Meeting.) A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, February 25th; SIR DUGALD CLERK, K.B.E., D.Sc., F.R.S., in the chair. Mr. EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, delivered the second lecture of his course on "The Effect of the War on the Economic Condition of the United Kingdom."

The lectures will be published in the *Journal* during the summer recess.

TWELFTH ORDINARY MEETING.

Wednesday afternoon, February 27th; The RIGHT HON. LORD FARINGDON in the chair. A paper on "The Organisation of Commercial Intelligence" was read by SIR WILLIAM H. CLARK, K.C.S.I., C.M.G., Comptroller-General of the Department of Overseas Trade (Development and Intelligence).

The paper and discussion will be published in the *Journal* of March 22nd.

CANTOR LECTURES ON "PROGRESS IN THE METALLURGY OF COPPER."

The Cantor Lectures on "Progress in the Metallurgy of Copper," by Professor H. C. H. Carpenter, M.A., Ph.D., M.Inst.M.M., A.R.S.M., have been reprinted from the *Journal*, and the pamphlet (price one shilling) may be obtained on application to the Secretary, Royal Society of Arts, John Street, Adelphi, London, W.C.

A full list of the Cantor and Howard Lectures which have been published separately, and are still on sale, can also be obtained.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s*. each, on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

TENTH ORDINARY MEETING.

WEDNESDAY, FEBRUARY 13th; ROBERT TOOTILL, M.P., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Chiura, Captain T., Osaka, Japan.
Davies, Rev. John Llanfair, Pembrokeshire.
Dilke, Sir Charles Wentworth, Bt., Brighton.
Frank, Robert, London.
Manville, Edward, M.I.E.E., London.
Moore, Thomas Cartlich, J.P., Stoke-on-Trent.

Nisbet, James Richard, London.

Rait, George L., Surbiton.

Ridge, H. Mackenzie, M.I.M.M., London.

Smith, C. Thomas, Nottingham.

Snell, Sir John Francis Cleverton, M.Inst.C.E., London.

Warnes, Arthur Robert, Hull.

The following candidates were balloted for and duly elected Fellows of the Society :—

Barron, William Alfred, M.Inst.M.M., London.

Bedwell, George Champion, Cambridge.

Brander, James, Bristol.

Britton, William, M.I.Mar.E., Aden.

Challen, Charles Hollis, London.

Elliott, Sir Bignell George, K.B.E., London.

Guild, John, Honolulu, Hawaii.

Hearn, John Edward, Luton.

Hind, John, Kohala, Hawaii.

Lewis, A., Honolulu, Hawaii.

Lidgate, Anthony, Hamakua, Hawaii.

Lucas, Harry, Birmingham.

Quittenton, Charles Henry, Warlingham, Surrey.

Searle, Richard Charles, Leicester.

Sen, Nirmul Chunder, London.

The paper read was—

"ZERO" OF CAPITAL AND LABOUR.

By Lord Leverhulme.

We are living in strenuous times and are making sacrifices of life and treasure on a scale that we are apt to believe is greater than our forefathers, even in their most difficult wars, were ever called upon to endure. But this is obviously only true of dimensions. It is not true of proportions to scale with the resources or wealth of the present British Empire as compared with her former war periods, nor is it true in relation to the resources science has placed at our disposal for our more rapid recuperation from the effects of this war by the exploitation and development of the nascent wealth that nature with lavish hand has stored up for us within our boundaries. To realise the natural strength of the British Empire let us think of it in the words of the poet—

"As some tall cliff that lifts its awful form,
Swells from the vale, and midway leaves the storm,
Though round its heart the rolling clouds are spread,
Eternal sunshine settles on its head."

Our most cruel and deplorable loss in this war is the awful sacrifice of human life, and the irreparable disastrous consequences to civilisation and the progress of the world that must result from so many of the flower of our manhood having been taken from us it would be impossible to overstate. This welter of blood has made the world one huge sob and stifled moan. There is not one single family group in the whole of the peoples of the belligerent nations that has not to mourn some loved dear ones lost, or returned mutilated and torn, blinded or crippled—the wreck and shadow of their former selves. No loving care nor patient toil can restore these or make good to us their loss.

But for the rest the loss can on certain well known and proved established lines be fully recovered, and most speedily of all the money wastage. Many worthy good souls are worrying themselves and the nation as to the undoubted load and enormous burden of national war indebtedness we shall have to carry when this war is over, and are worrying still more as to our ability as a nation to repay these debts. In their alarm, and suffering from an attack of nerves and cold feet, some openly advocate unblushing repudiation of our war debts, and call this by some such specious name as Conscription of Wealth. And in their haste to propound this "cure all" for our ills they cannot even wait until we have won a decisive victory on the battlefield and obtained the unconditional surrender of our enemies, but must needs weaken the national credit by advocating this impossible policy even whilst the necessity for further borrowing still continues.

There are seven pillars of national and individual prosperity and happiness. These are: Justice, truth, labour, capital, science, art, leisure.

The unit of the Empire, as of all democracies, is the home and fireside, and along the lines defined by the seven pillars of prosperity individual nations and the home units have progressed from slavery to fullest liberty. What were the conditions of life in Great Britain in, say, Oliver Cromwell's time, when we experienced our greatest advance towards our present ideal form of Government—a constitutional monarchy? London even then was the largest, the richest, and most populous city in the then known world. Yet it was indescribably dirty, overcrowded, insanitary, badly lighted, and worse drained, and neither health nor life was safe from attacks from disease, pestilence,

or robbers and footpads. The death-rate was over 49 per thousand in ordinary years, and much higher in years of special visitations of plague. In Oliver Cromwell's time close to London were twenty-five square miles of swamps, which to-day are absorbed within the boundaries of the metropolitan area, drained dry and made healthy and built over. In wet weather the streets and roads were impassable, a quagmire of mud in which chariots, waggons and carts sank to their axles. Robbers, footpads, and highwaymen made it dangerous to travel in daylight, and impossible at night to do so without being under convoy of a guard. In the United Kingdom at that time there were thirty-four counties without any, even the most primitive, form of printing-press. The master flogged his apprentice and the husband flogged his wife. The stocks, the ducking-stool, and the whipping-post were national institutions in the most public centres of every town and village. Even a century later we were very little improved in our social life.

What has changed all this to conditions such as exist in the United Kingdom to-day? It has been the discoveries of science and the inventions of mechanics. About the close of the eighteenth century, Watt, Arkwright, Hargreaves, Crompton, Cartwright, and others, invented various of our most important "key" mechanical utilities—such as the steam engine, the spinning jenny, the mule, the power loom, the carding machine, and scores of others. It is said that, as a result of these inventions, twenty-five men and fifty women and boys can produce to-day as much cotton goods as could have been produced by the hand labour of all the men, women and boys that were engaged in the cotton industry in Lancashire in Oliver Cromwell's time.

And what is the condition of London to-day? The population is more than a scorefold what it was then, and it has become the cleanest, most healthy and sanitary, the best lighted and the best drained city, as it is also the largest city, in the world. And all traces of special visitations of plague or pestilence have ceased, and the death-rate is the lowest of any of the largest cities of the world, being no more than 15 per thousand.

And corresponding progress has been made in every city, town, and village in the country, and in the social betterment of the lives of the people, and the British Empire has become the greatest Empire in the world, not by repudiation of the Napoleonic war debts, not by Acts of Parliament, but by the steady maintenance of the beneficent support of the seven pillars of prosperity, and by the labour of employer capitalist, and employee workman. These, as inventors, manufacturers, merchants, explorers and shipowners, have often been handicapped in the march of progress in competition with other nations by stupid Acts of Parliament and ignorant statesmen; but, in rectifying this handicap of progress, let us be careful that we do not commit still greater errors of government in the future. Our best hope for the future is that the whole of the difficulties to be overcome, and of our social betterment to be achieved, shall be fully considered in all their bearings, shall be fully discussed and understood before we enter upon the putting into effect of immature and ill-considered new and experimental policies. We must approach the consideration of the problem with minds free from thoughts founded on prejudice, hatred or temper, free from taint of selfishness or injustice. Above all, we must dismiss from our minds and souls any idea of what, for the want of a better name, we call "class against class" antagonism. In all countries throughout all ages there have been numerous divisions of peoples into so-called "classes," but this good old world, large as it is, has never been big enough to contain more than a division into two great classes—the class that is doing its duty and the class that fails to do its duty. These two great divisions are wide enough and deep enough to include the whole human race, and all other distinctions are purely artificial. But we have got into a slipshod way of thinking of mankind as existing in "classes," and nothing, in the present temper of the world, is more unjust or dangerous. Peer and peasant, employer capitalist and employee workman, have fought side by side in the trenches and laid down their lives side by side on the battlefield in this great war, and as comrades in this war they honour and respect each other as never was possible before; and we have all learned that in about equal proportional numbers there are included, in all the artificial "class" divisions, the industrious and the idle, the intelligent and the stupid, the brave and the cowards, the honest and the cheat, the truthful and the liar, the virtuous and the vicious, the temperate and the drunkard, the strong and the weak, the healthy and the sickly, the thrifty and the spendthrift, and that so long as these opposites of characteristics exist there will always be the rich and the poor. Let us uproot this habit of

thinking of individuals according to certain artificial so-called "classes." Nothing is more unjust and nothing could be more dangerous.

Long before this war began we were experiencing the influence in politics of a new Parliamentary Party whose leaders scorned the beaten tracks of old-school politicians and who called themselves the Labour Party. The employee workmen, through their trades unions, have also become more active, and have rightly and properly—so long as they respect the just rights and liberties of others—organised to improve their position. The betterment of the condition of the employee workers is declared, and I believe truly so, their sole objective and goal, but so far as my knowledge goes the employee workers have not yet unanimously decided upon what might be the best methods for them to adopt to realise betterment and advancement. In short, whilst their aims, ideals and ambitions are clear and definite, their proposed methods for realisation are most indefinite and hazy.

When the dissatisfied colonists in North America won, under the leadership of General Washington, their severance from Great Britain nearly a century and a half ago, they declared as their ideals—and in these the whole English-speaking world agrees to-day—that all men were endowed by God with certain inalienable rights, amongst which were life, liberty and the pursuit of happiness. Washington and his co-founders of the United States believed and trusted that if all men were given an equal opportunity, and if the citizens of a country could frame their own laws and levy their own taxes, the inequalities in wealth that existed in the Mother Country could never exist in the United States. This was the view held in 1776, and the founders of the United States were convinced that the rich and wealthy were rich and wealthy in consequence of some unfairness in the laws of the United Kingdom. But, after nearly a century and a half—in spite of the Declaration of Independence as to equality, in spite of universal manhood suffrage—there are greater inequalities of wealth in the United States to-day than there are or ever were in the United Kingdom, and it is clear that neither Acts of Congress nor the Constitution of the United States have been able to make all men equal in wealth any more than in health, weight or stature, brains or muscle, piety or morals, character or worth. But this inequality of wealth, although infinitely greater in 1916 than in 1776, at which time, as often is the case to-day, it was thought to be the cause of all the poverty of the poor, has been proved to have relieved the extremes of poverty and wretchedness, to have greatly raised the average of comfort and betterment, and to have resulted also in actually a better distribution and more plentiful supply of wealth amongst the employee workmen. The United States has produced millionaires in greater number and of greater individual wealth than ever the United Kingdom produced, and yet the employee workman in that country receives the highest rate of wages known in the world. In 1776 it was believed that in the United Kingdom the Government had somehow interfered with some great principle underlying all social well-being, and that in the United States, under the Constitution adopted in the Declaration of Independence, wealth would be more equally distributed and poverty would cease. But the result has clearly proved that so long as some men are stronger, or more healthy, or more intelligent, or more industrious, or more virtuous, or more self-denying, or more thrifty than others, that there will be inequalities of wealth, and that the employer capitalist was not responsible for this, nor was the employee workman to blame, and that if either changed places with the other by Act of Parliament, that change over would constitute no remedy for acknowledged inequalities nor be a stimulus to social betterment for all. Employer capitalists, in acquiring their wealth by hard work of brain and energy of body, have benefited not only themselves and their families, but have, even if unwittingly, conduced to the betterment of the employee workman and also to the progress of the whole of the industries of the United Kingdom.

And now I venture to assert that, notwithstanding that all the above circumstances are inevitable and normal and natural, still no employer capitalist with a true feeling of brotherhood can be quite happy in the fullest sense in the enjoyment of wealth—the product of his own hard work, intelligence, self-denial and thrift, every penny earned without committing injury to any man, and the acquisition of which has resulted in enormous benefits to his employee workmen — without feeling a sense of dissatisfaction with present industrial conditions and a strong desire to improve them so that the employee workman may be raised to a much higher level in social well-being.

But this idea cannot be achieved by an Act

of Parliament for the conscription or confiscation of wealth.

The men and women of British stock who crossed the Atlantic and founded the United States did not state in their Declaration of Independence that all wealth must be confiscated to the State. What they did declare was that man was endowed by God with certain inalienable rights of life, liberty, and the pursuit of happiness. Do these rights mean that Government should conscript or confiscate the fruits of the industry of one man who had led a thrifty, wholesome, industrious life, in order that Government might use the same for the benefit of men who had lived lives of exactly the opposite type? That was certainly not what the citizens of 1776 ever intended. What was meant was that every citizen had the fullest liberty to live his own life and to make his own livelihood in his own way so long as that was honest and true, and that he was entitled to the full enjoyment of the product of his labour, whether of muscle or brain, and for the pursuit of his own happiness—also within honest and true limits—in his own way.

And what was meant by liberty? One of the best definitions of liberty has been stated by—if I remember correctly—a French Convention in the following words—

"The liberty of one citizen ceases only where it encroaches on the liberty of another citizen."

And as to the pursuit of happiness, John Bright has given us one of the best definitions of happiness—

"Happiness consists in a congenial occupation with a sense of progress."

In addition, this Declaration of Independence laid down the axiom that Governments were instituted to preserve these rights to the people, and that the people themselves were the source of all the power that Governments possessed. The force that has created the United States has not been Congress, nor was the British Empire built up by Parliament. There would have been no United States and no British Empire without the labour and toil and sweat of the people of the two nations. Governments create no wealth as such, and possess no money but what they receive from the taxation of the people. All Governments are paupers, and only exist in free democratic nations by the consent of the governed. All Governments being paupers they have only two means for raising money—by taxation and by borrowing. In times of war, or for great public undertakings such as waterworks, or municipal developments such as docks, etc., borrowing has had to be resorted to in the past years as in the present years, and will have to be resorted to in the years to come when this war is over. The power and ability of a Government to borrow and the rate of interest to be paid depend entirely on the credit of the Government concerned, and on the assured belief of the lenders in the borrower's ability and good faith for the due payment of interest and the repayment of the debt. Our British Imperial and Colonial Governments and our municipalities have hitherto enjoyed the power to borrow all their requirements at the world's lowest rate of interest. This advantageous position is entirely due to public confidence in the honour, honesty and good faith of our Governments. If we once shake confidence in either our ability or our willingness to repay our indebtedness, then our credit and power to borrow is either seriously damaged or may be hopelessly destroyed. And with this destruction of credit and confidence would come equally the ruin of our industries, and unemployment and hunger would be our chronic condition. If we, as British citizens, cannot realise these truths then we are in greater peril than if the Prussians had landed on our shores and were marching through an undefended country on defenceless cities and towns. The British Empire might recover in time from defeat in war, but the British Empire never could recover from its own default to repay its war loan indebtedness. The credit and confidence enjoyed by the British Empire is the one and only foundation on which stand four-square to all attempts to overthrow them the prosperity and stability of British industries, and ability to provide full employment at full wages for the British workman. The repudiation of debt, or the so-called conscription of wealth, would be an assassin blow at the very heart of the British Empire.

But even if it were a practical and honest policy there would be two questions still that would arise and require to be answered—how could such conscription be accomplished, and what would it yield? The suggestion is that we conscript sufficient of the wealth of the country on some graduated scale to enable us to repay at least £4,000,000,000 of war loan indebtedness. How would our Government collect this £4,000,000,000 and convert it into cash — for it is obviously only

as cash that wealth could be used for the repayment of war loans? At present this wealth exists in the form of furniture, pictures, china, works of art, houses, land, workshops, factories, machinery, ships, horses, cattle, sheep, and the thousands of other forms of wealth, including debentures, shares, mortgages in public railways, industrial companies, municipal and dock loans, Government war loans, deposits in banks and building societies. And this wealth includes the savings of the frugal father for his widow and children equally with those of the millionaire. We know the depreciation that takes place when trustees are forced to sell some portions of an estate in order to pay death duties. But only some £30,000,000 a year are paid in death duties, and much of this we know has been received by the trustees in hard cash from banks and insurance companies. It is only a cautious estimate to assume that not more than two-thirds had to be raised by forced sales—say £20,000,000 a year. But to realise even this modest sum each year has tended to depress the market value of securities. So that it is clear that no market could be found for £4,000,000,000 of conscripted wealth at what I may call par value, and as practically everyone with wealth would be a seller, and there would be almost no British buyers, it is only reasonable to say that the £4,000,000,000 of conscripted wealth would not realise in cash as much as £400,000,000. It would be almost valueless and unsaleable, and therefore not available for the purpose intended of repaying war loans. The confiscation of wealth would carry the country, ice-bound, below zero. Left to fructify in the pockets of its owners, it would produce its yield in income tax and death duties to the State, and in employment for employee workmen, not only of the then existing factories and workshops, but still more important, of extensions and additions thereto, and for the provision of capital for working and building the same, to be obtained on the credit of the security available. But conscript 10 per cent. or 20 per cent. of the wealth of the country, and not only would the conscripted portion be unsaleable, but the balance would be depreciated as security for credit to finance our industries to the lowest level of the conscripted portion. This would be like cutting out the roots of the tree to anticipate the next year's crop of fruit.

But this cutting out of roots is certainly not what wise men would do. They would guard the roots, fertilise them, prune the dead roots, support the limbs and branches, protect from frost the blossoms, and finally reap an abundant harvest—growing larger in quantity and better in quality each year of patient care and cultivation. Therefore our course for repayment of war loan lies in cultivating our industries and fertilising them—root pruning by death duties, and collecting the harvest by means of income tax graduated so that all citizens with incomes of £80 a year and over contribute according to their means. In no other way can we realise so large a cash income to pay off our war loans so speedily and quickly, maintain British shipping and industries, find ever-increasing employment for British labour, and maintain British credit and the pre-eminent present position of our world-wide British Empire.

It may be asked how steeply can income tax and death duties be graduated; the answer can only be that if our needs require them, then the only limit can be that point at which they yield the largest return to the State with the least injury to our industries. If income tax at 5*s*. in the £, and death duties at 20 per cent., yield the largest return to the State with least injury to our industries, and if income tax at 10*s*. in the £ and death duties at 50 per cent. would yield actually less to the State, and would also threaten our industries with ruin, then the lower figure without risk to our industries would have been proved to be the only practicable rate. In other words, at the high rates you would be killing the tree that bears the golden fruit.

Every farmer and gardener knows that such a hint as decreased yield from nature as to the limits of cropping, if disregarded, sours the land and the plants, with ruinous results. The reduced yield from the higher rate would also prove that trade and commerce, house-building, ship-building, and our manufactures were suffering from being denuded of capital by excessive taxation, and that unemployment would soon be stalking, with famine and sickness, through our land. And we should find that a just, fair, and reasonable scale of graduated taxation will not only yield the largest amount of cash to the State, but that the remainder, left to fructify in the pockets of its producers, will act as a stimulus to the production of ever larger and larger taxable incomes, and to the employment of an ever-increasing number of employee workmen by employer capitalists to the expansion of British

shipping trade and commerce, and to the maintenance of our present pre-eminent position amongst the nations of the world. So graduated income tax has its zero point.

"All that freedom's highest aims can reach
Is but to lay proportion'd loads on each.
Hence, should one order disproportion'd grow,
Its double weight must ruin all below."

No, there is only this one way available to enable us to repay our war loans, to re-establish our mercantile marine, our trade, commerce and manufactures after this welter of a world war, and that is to stimulate the production of wealth and to tax the annual income to the limits of utmost yield, but always so that the producers of wealth are encouraged, stimulated, and are left with the necessary means for the production of more wealth. This production of increased wealth will demand and necessitate that every adult man and woman of all classes shall, up to the limit of his abilities and capacities, work hard and strenuously for its production. But human strength has its economic zero point also. If in the production of this wealth either the employer capitalist or the employee workman is over-fatigued by working a longer number of hours than the limitations demanded by health and strength, then the result can only be disastrous to the production of wealth. But if all adults, of both sexes and of all classes, peer and peasant, employee capitalist and employee workman, work each a reasonable number of hours per day, then, without over-fatigue of any, we can produce a wealth of products sufficient for our own home markets and wants and for overseas exportation, far in excess of anything we have ever previously accomplished. The exact number of hours that will produce overstrain and fatigue, with resulting lower production, will obviously vary with the nature of the occupation and with the conditions under which the work is performed. On the farm, for instance, and on board ships, surrounded by green fields or green ocean and fresh air, the hours worked may presumably be longer than would be possible in factories, mines, workshops, foundries, offices, or stores, where perfect ventilation is never quite attainable, and where the occupation is more or less monotonous. But in every kind of work and employment there must be some limit to human strength and endurance, and experience has taught us that between eight hours a day as a maximum and six hours a day as a minimum, the safety point may most probably be found to rest. These hours of daily toil are what may be called the income-making period—the remaining hours are available not only for sleep, eating, recreation and leisure, but also for education and public service and all the refinements of life. St. Paul has told us that he "laboured with his hands that he might be chargeable to no man," and we know that he was by trade a tentmaker. The hours of labour for tentmakers were, I am told, at that time from 5.0 a.m. to 11.0 a.m., that is six hour per day, and the remaining hours St. Paul devoted to his life's work—service to his fellow man. Let us organise our time better. At present all our time is devoted to gathering income for maintenance as if we were so many cows and sheep, all of whose time we know is devoted to the work of maintenance. Our factories, foundries, mines, workshops, stores, offices and farms throughout the British Empire are full of men or women with ideals and ideas for utilities and inventions, and who, in addition to their capacity for the work of income-earning for maintenance and support of themselves and families, are capable of, and keen for, work of enormous social value to their fellows and the Empire. What a wealth of inventive genius and ideas have we there running actually to waste through our bad organisation of their hours of work, and their subjection to overstrain and fatigue in the performance of the daily round of routine duties for income producing. Under our present system each day has to be fully occupied in reaching the fatigue limit in work for income for maintenance, with the result that our machinery is underworked and our workers are overwrought, giving us less wealth produced at greater cost than need be the case. Thought and ideas for new inventions and processes require intelligence, alertness and leisure—all impossible under conditions of over-fatigue during long hours of laborious toil. Then see how the wage and salary fund is impoverished. We can only work our machinery and mechanical utilities longer hours by working human beings fewer hours. We have already exceeded the limit of human endurance from school age to dotage. But if we reorganise our factories so that by working a number of change shifts of employee workers six hours each shift we can run our machinery twelve, eighteen, or twenty-four hours each working day. The wages paid at present for longer hours would require to be paid for the fewer hours, and in order to do this the total cost of production, which is partly

interest, depreciation and repairs for machinery —all of which would be little if at all increased by the additional hours worked—would on an increase of from 50 per cent. to 200 per cent. in the output give us lower costs, out of which wages could be increased and selling price to customers reduced. And believe me it is impossible to lay too strong emphasis on this crux of the whole proposal, which is the one and only basis which would make reduced hours and higher wages possible—namely, reduced final costs and lower selling prices for the consumer, with more wages to the worker and fewer hours of toil. The employer capitalist could, of course, work with a lower percentage of profit and yet realise on his increased production a larger income to meet the demands made upon him for higher graduation in rates of income tax.

And now let me say a word on the value of a better organisation of time devoted to income-earning in its effect on education of brain, body, and mind, and the power it would give the State for training citizens for military service. In all change shifts the shift workers who one week worked in the morning would the next week work in the afternoon, so that there would be for everyone the morning or afternoon free each week alternately. From fourteen to eighteen years of age there would be for boys and girls two hours morning or afternoon each day required by the State to be devoted to higher grade education and physical training. From eighteen to twenty-four the State would require that these two hours be devoted each day to technical and higher education such as is provided to-day only in our universities, and for physical training, and from twenty-four to thirty years of age the State would require that these two hours each day be devoted to military training and preparation for National Service. After thirty years of age the citizen would have completed his period of compulsory attendance under State regulations, and would be fully equipped by education and training for all the duties of citizenship; and might reasonably be trusted to make, as did St. Paul, but in his own way, his own voluntary contribution to social advancement and betterment.

But in addition to a better organisation of time in our industries, we require to advance still further in the direction of a more logical basis in the relationship between the employer capitalist and the employee worker. There must be some consideration given to the division between these two of the profit resulting from the joint labour of both. The wages system alone is not sufficient, but the wages system must of necessity remain the basis for the employee worker. It is a system that has stood the test of time; it is convenient; it is logical and practicable. Under the wages system the employee worker practically says to the employer capitalist: "I cannot undertake to bear any of the risks of this business. I must receive a weekly or monthly income, regularly, upon which I can absolutely rely and depend for my household expenses: therefore, if I engage with yourself, we must mutually first agree on a sum which you shall pay me as wages or salary in exchange for my services. If, after paying this sum of money to myself, and also after your payment of all other expenses of the business, there is a profit remaining, I agree that that profit shall be yours. If there is a loss you must make that loss good yourself alone, even to the extent of bringing ruin and disaster upon yourself and your family. I cannot share with you your losses, and I agree to make no claim upon you to share in your profits." This, I repeat, is the logic of the present wages system, and it is perfectly sound and just in its basis and principles.

The admission to co-partnership is not a right that the employee worker can of necessity claim. It is obvious that there must always be the right with each of us to choose our partners by mutual consent, if the true co-partnership spirit is to be maintained. The employer capitalist can choose his partners, and does choose them from those who can give him the best help and can best strengthen his business, either by contribution of capital or assistance in the management of the business; and in making this selection of partners every care and effort is directed to avoid entering into a partnership that may prove undesirable in practice. The happiest and most successful relationships in business life have been realised under the partnership system, and it is equally true that occasionally, from various causes unforeseen at the time, private partnerships have proved disastrous, both from the point of view of prosperity of the business, or the happiness of the partners. But the intention has always been the same—namely, to help and strengthen the business and to share the responsibility and risks of the business between the partners. I am confident that, viewed in this light and not as a profit-sharing device, which in my opinion would be wrong,

co-partnership relations with the employee worker would be an added source of strength to any business to which co-partnership could be applied, and would increase the prosperity and happiness of both the employer capitalist and the employee worker. The application of the principles of co-partnership between these two is just as sound and practical a business arrangement as between any body of partners, and one that might just as wisely be entered upon.

Under the operation of our modern industrial developments, capital is generally raised from a body of shareholders, in the form of ordinary shares. These ordinary shareholders divide amongst themselves the total remaining profits of the business after payment of all claims for salaries, wages, interest and other prior charges. The ordinary shareholders of a company are practically the partners who control the destiny of the company by their vote, but it is very rare for any of them to be engaged actively in the business as employee workers. It can never be a source of strength to the business that the whole of the surplus profits, after paying a reasonable and proper rate of interest, should be entirely devoted to dividends to ordinary shareholders. I am convinced that the best interests of the ordinary shareholders would be better served, both in regard to the rate per cent. of their dividends and the security of their capital, if the surplus profits could be divided, under some scheme of co-partnership, between the employee workers and the ordinary shareholders of the business.

It is not in the best interests of the success of any business, nor of the progress and development of British industries as a whole, that the entire surplus profits should take only one channel, and that channel a direction away from those most interested in the business, and upon whom must depend the continued success of the business. It would not be right to view this question of co-partnership from any benevolent point of view. There can be no philanthropy in business. But the cultivation of a spirit of co-partnership, and of a keen interest in the firm in which the employee workers are engaged, is not philanthropy but sound policy. The whole of the goodwill of any business, which goodwill is often of greater value than the actual bricks and mortar, plant and machinery, depends on mutual confidence. The employer capitalist and ordinary shareholders to-day view the employee worker solely as a liability. Employees are not liabilities, but the most valuable of all the assets of any business.

An objection often raised to profit-sharing, and, I think, rightly raised, is that there can be no loss-sharing. Under the system of co-partnership, loss-sharing can be linked up with participation in profits. After all, what are the losses of capital for the employer capitalist? His losses of capital are that certain shares that he holds, by purchase or original application and payment, have become valueless because they have ceased to have earning capacity. One has often heard of shares in some company that has entirely lost its earning capacity, being only fit to make into spills to light cigarettes with — their capital value has become *nil*. Equally, the co-partnership certificates issued under a scheme of co-partnership to the employee workers would be only fit to make into cigarette lighters, and absolutely valueless, if the power of the business to earn profits had ceased, notwithstanding all the efforts of employer capitalist and employee co-partner.

It is quite obvious that, under a system of co-partnership, whereby an employee worker receives each year an allotment of co-partnership certificates in proportion to the amount of his salary or wages, and the length and value of his services—which co-partnership certificates are, during the co-partner's connection with the firm, entitled to dividends in proportion to the dividends paid to the ordinary shareholders—the co-partner would see the number of co-partnership certificates growing each year. He would experience the fact and would realise the cause why dividends some years were higher than others, and why some years, from unavoidable causes, dividends might fail to be earned or paid. He would realise the direct connection between profits and all the problems that the management have to solve in a business, and in this way the employer capitalist would have secured a partner whose brain would be at work as well as his hands, in effecting economies and avoiding waste in the business, and in making suggestions for the improvement of processes and improvement in the organisation of the time of himself and comrades, so that profits might be increased and higher dividends be paid.

I claim that the employer capitalist is not reasonable if he expects, in exchange for wages, any more than the performances of the services which he has contracted for. But, in addition to services that could be rendered on a wages

system, there is that constant thought and care, outside business hours just as during business hours, for the good of the business which the employer capitalist himself does constantly manifest, otherwise his capital would be in danger and his dividends might never materialise.

Under a system of co-partnership the employer capitalist would have all his employee workers, who had been with him a certain number of years, as co-partners now realising that their interest in the business, equally with that of the employer capitalist, ran along the lines of increased output and of cheap cost of production, and there would come what I may call "team-work," which in the Army is, as you know, called *esprit de corps*, which results in a spirit of comradeship in overcoming all obstacles, and which is specially manifested in times of difficulty and danger.

Had time permitted I would have liked to have amplified many other aspects of the advantages to our industries that would be derived from co-partnership, but I have already transgressed on the limits of your patience. I may just say that to anyone specially interested in co-partnership I should be very glad to send copies of many addresses I have given on this subject which deal much more fully and completely with this great subject than is possible in the time available on this occasion.

But whilst my endeavours have been to record the views I hold, and hold very strongly and sincerely, that Governments of themselves cannot create wealth, that the power of Governments to confiscate or tax wealth is strictly limited within the range of such rates as will produce the largest cash income for the service of the State without danger of check or hindrance to the production of wealth and opportunities for employment; to show that we shall require the labour of all adults of both sexes and of all classes from peer to peasant to repay our war indebtedness and to provide products for home consumption and for exportation overseas, I have endeavoured to show that work also has its limitations of profitable production, and that to overstrain employee worker or employer capitalist is not to produce the best results from either. I hold equally strongly that Governments can render such services of the State as will furnish opportunities and facilities, encouragement and stimulus, for the creation of wealth by the citizens who have entrusted the State with powers of government. The State should and could make concentrated and well-considered efforts to provide every facility for honourable enterprise and honest industry. Our mercantile marine must be protected at sea and provided with ample harbour and dock facilities in the ports of the Empire. Shipowners, manufacturers and merchants must be encouraged and helped by an efficient Consular and Foreign Office service, so that our ships may sail over every sea and our flag be flying in every port. The State can improve our banking system by encouraging and stimulating our bankers to render increased credit facilities for the manufactures, trade, commerce and mercantile marine of the Empire. In our Crown Colonies our Government can construct roads and bridges, build railways, open up new and rich territories of virgin forests, fertile soils and rich minerals, to developers, planters, and traders on terms that would encourage and justify private enterprise in the investment therein of capital. The State can improve the sanitation and healthiness of our villages, towns and cities at home and in the Colonies, and so not only lengthen human life but reduce the toll on productiveness caused by ill-health. Government can protect child-life and see to its welfare, and can improve our educational system so that we get the utmost in the finished product for the many millions we spend upon education, so that the child of the employee workman can have the opportunity of becoming as well educated as the child of the employer capitalist. Government can remove all incidence of taxation and rating, local or Imperial, from improvements on land such as houses and buildings of all kinds, and from machinery, and provide that all such taxation and rating shall, in future, be provided from local and Imperial income tax source, and on site values. All obstacles, in short, for the development of the resources of the Empire at home and overseas must be removed, and every facility, encouragement and security be given to stimulate the production of wealth. Otherwise, what right or title have we members of the British race at home and overseas in the possession and enjoyment of a world-wide Empire on which it is our boast that the sun never sets? If our Government is not sufficiently far-sighted or so wise as to foster facility and encourage great industries capable of producing enormous surplus wealth by the enterprise of her citizens within this world-wide Empire, which would not only find employment for all, but provide a basis for taxation of incomes that would enable us to

repay our war debts, then the British Empire is suffering from the palsy of old age and we shall soon cease to exist as a world Power. Empires rise and fall as they are well and wisely or badly and stupidly governed. Under wise government they become rich and powerful, their ships sail over every sea and carry the national flag into every port; their colonies cover whole continents; their peoples are happy and contented, well housed and well fed, and not overwrought to maintain themselves in comfort in homes where, with wife and children, life lengthens and joy deepens; their rulers and statesmen are honoured and respected by surrounding nations, who can view without bitter feelings of wrong to themselves a world-wide Empire wisely governed with every facility and opportunity, and where welcome is given to all right-minded citizens of all right-minded nations. Nothing can be better for the progress of civilisation and the well-being of the whole world than such a government of such an Empire. And it must with equal truth be stated that there can be no more pitiable sight in the whole world than such an Empire held and possessed by a nation that has neither the vision nor the intelligence to develop wisely or govern justly. "Where no vision is the people perish."

DISCUSSION.

THE CHAIRMAN (Mr. Robert Tootill, M.P.), in opening the discussion, said he thought all present would agree that the paper was the finest exposition of the subject that they had ever heard or read. Speaking as one who had been more or less in the front-line trenches of the labour movement for forty-six years, he considered that the paper ought to be printed in pamphlet form and distributed broadcast amongst the workers of this country. It was very easy to talk about conscription of wealth. The man in the street and the man in the workshop naturally thought that the wealthy classes were not doing their fair share towards the maintenance of the war, and that they by their labour were contributing more than the wealthy classes. Conscription of wealth appeared to them to be a plausible scheme, but the difficulties of applying it without ultimate injury to themselves were very serious indeed. A great deal of ignorance existed on the subject at the present time, and the paper had shown what would be the real results of the conscription of wealth which was suggested by many of the Socialist and Labour leaders of the country. If it was to be carried out equitably it must apply all round, and there must be no partial and discriminating legislation. There was said to be one law for the rich and another for the poor, but that was only true to the extent that the rich were able to pay better equipped and more intelligent counsel to plead their cause. People had the power within themselves to make the best of their physical and mental resources. They were all human beings and to that extent started equal, and their environment, training, opportunities and privileges made most of the difference. He was glad to hear the author describe workmen and employers as comrades, and point out that there was need for greater dissemination of mutual confidence between them. His (the Chairman's) own policy for removing the doubts and suspicions that at present existed between them was that there should be selected from the various departments of firms the most intelligent and capable men, who should be taken into the board-room and into the office, not to override or to dictate, but to discuss with the employers the difficulties of the various propositions put forward. Then those workmen should go back to their comrades in the workshop and explain the difficulties to them. He might mention that the Minister of Labour had asked to be furnished with a copy of the paper, and that he had told him he would find it extremely useful to study.

MR. LEWIS HASLAM, M.P., agreed with the Chairman that the paper ought to be distributed widely throughout the country. It should be read by employers and employed, and also by the heads of the Government. The development of character was of the utmost importance at the present time; everyone wished that people in the future should be honest citizens, and that goodwill should take the place of suspicion and distrust. Ignorance was the cause of all the trouble that existed at present between class and class, and until it was dispelled there would always be that suspicion which created distrust and was the enemy of progress. There was much misunderstanding, for instance, on the question of the proportion paid by the wealthy classes towards the cost of the war. He had worked it out the other day, and had come to the conclusion that four-fifths of the money now paid into the Exchequer came from the income-tax paying classes, who now had a spending power of not more than one-third of what they had in pre-war times. If employers and workmen put their heads together, and worked loyally together, the wealth of the nation could easily be increased by 50 per cent., or £1,200,000,000 a year. Lord Leverhulme had not touched on the question of improving our transport system, but personally he thought there ought to be some means of amalgamating the various systems, so that the best use might be made of the canals and railways of this country, and the present competition between them be avoided.

SIR SWIRE SMITH, M.P., said the paper had opened up a vision of what the country could do, even under the present difficult circumstances. About thirty years ago, after the inquiry of the

Royal Commission on Technical Instruction, of which he was a member, and which began its work in 1881, he was invited by the Society of Arts to read a paper on the Technical Education Bill. Two or three years after he read that paper the present Technical Instruction Act was passed, and he believed that technical instruction had saved the industries of this country. Before that Act was passed this country was behind its competitors in every direction, and our educational system was deplorable. Mr. Forster's Education Act had only been adopted by a proportion of the country, and there was not a single well-equipped technical school in the length and breadth of the land. Since then a great improvement had taken place, but even now we were surpassed by other countries in many subjects. We were still behind some countries in everything connected with science, for instance, because we had not given the attention to the subject which we ought to have given. A great improvement would take place if this country followed the advice given by the author in his paper, if it determined that Mr. Fisher's Education Bill should be passed, and if it insisted that all boys and girls between the ages of fourteen and eighteen should attend school for a certain number of hours a week, devoting time to the study of citizenship and all those things which they required for their physical health and mental and moral development, and that after the age of eighteen they should continue to give a portion of their time to the higher branches of technical instruction in art as well as in science.

Mr. Robert Applegarth, speaking as one who had travelled abroad a great deal and had studied the educational and industrial systems of other countries, thought that the question of education was of far more importance than any of the other subjects dealt with in the paper. The State should be made to recognise the fact that it must feed, clothe, educate and train all its children. If all children were given equal opportunities and a proper education, people would begin to find that the working-classes would not need lecturing. He was convinced that if the people of this country were given the education to which they were entitled they would then settle the whole of the details put forward by the author, and would produce for use and not for profit.

On the motion of the Chairman, a vote of thanks was accorded to the author for his interesing and useful paper.

Lord Leverhulme, in responding, desired to accord the thanks of the meeting to the Chairman for presiding. He thought the Chairman had struck the right note when he emphasised the necessity of removing the suspicion and distrust that at present existed between employers and employed.

The meeting then terminated.

OBITUARY.

Earl Brassey, G.C.B.—The Society has lost an old and much valued Fellow by the death of Earl Brassey, which took place at his residence in Park Lane on February 23rd.

Thomas Brassey was born in 1836, and was educated at Rugby and University College, Oxford. He entered Parliament as Liberal member for Liverpool in 1865. From 1868 to 1886 he represented Hastings. In 1880 he joined Mr. Gladstone's Government as Civil Lord, and was afterwards Secretary, to the Admiralty. He was created a K.C.B. in 1881. In 1886, after the defeat of the first Home Rule Bill, he withdrew from the constituency of Hastings and offered himself as a Gladstonian candidate for one of the divisions of Liverpool, but he was defeated. On the resignation of the Government he was raised to the peerage. In 1895 he was appointed Governor of Victoria. In 1906 he became a G.C.B. From 1908 to 1913 he was Lord Warden of the Cinque Ports, and he received an earldom in 1911.

It is hardly possible to think of Lord Brassey without associating him with his famous yacht, the "Sunbeam," in which he travelled over 400,000 knots, and which, after her owner had made his final voyage in her to India, was in 1916 handed over to the Indian Government for permanent use as a hospital ship.

Lord Brassey's connection with the Royal Society of Arts was of very long standing. He himself became a member in 1862, and six years earlier his father, Thomas Brassey, a well-known contractor for public works, who constructed railways in many parts of the world, had been elected. Lord Brassey served on the Council, with few breaks, from 1871 to 1882, and again from 1913 to 1915. He was also a member of the Colonial Section Committee for many years, and remained on it up to the time of his death. He was frequently present at the Society's meetings; he presided on several occasions, and often took part in the discussions.

GENERAL NOTES.

The German Mercantile Marine.—Some of the largest German shipping firms, according to *Engineering*, have recently placed orders with German yards for over 150,000 tons. This is, no doubt, the first effect of the new German merchant navy aid measure, and the fact of the first instalment of 300,000,000 marks having been asked for. Another step for the financial assistance of German shipping is the impending creation of a ships' loan bank, with an initial capital of 10,000,000 marks, subscribed by some of the leading banks. The new bank is not intended to confine its activities to sea-going vessels, but will also assist river traffic. The Oder yard in Stettin is again increasing its capital so as to raise it to 4,000,000 marks.

MINERALS IN SIAM.—Mining engineers who have recently visited the Southern Siamese Malay States have come to the conclusion that it is one of the richest mineral areas in the world. In addition to wolfram, rich deposits of tin alluvium are found in the valleys and gullies of all the hills in which wolfram has been found, says *Eastern Engineering*. In most of the hills the number of wolfram lodes already located exceeds ten, and in all of them tin has also been discovered. Plenty of water with sufficient head is said to be available for washing out the tin in the rainy season, and there are possibilities for storing water in reservoirs for the dry season. There is a waterfall close by with sufficient head to develop electric power for working a large number of mines. In Northern Siam mining areas adjoining the new railway extension have been opened, and there antimony and lead are worked, the lead being mixed with zinc and containing some silver.

GAS TRACTION.—Evidence has been laid before the Gas Traction Committee by manufacturers of flexible gas containers, according to which about 4,500 commercial motor vehicles have been equipped to use coal gas instead of petrol. Orders for an additional 2,500 flexible containers, all for business vehicles, are in hand for completion during the next few months. The evidence shows that under 4 per cent. of the total deliveries to date have been to owners of private motor cars, that no further orders in this category are being taken, and that practically the whole of the manufacturing processes are being carried out by woman labour. The estimated saving of petrol is already at the rate of, approximately, 3,000,000 gallons a year.—*Railway News*.

OSTRICH LEATHER.—Last year a tanned ostrich skin was sent to the South Africa Trades Commissioner, who obtained the following report from one of the most expert fancy leather tanners in the United Kingdom: "The most likely purpose we could suggest for such would be dressing-case work. Its unusual appearance on the exterior of travelling bags would attract a class of buyers who like their luggage to have a *distingué* appearance, and willingly pay the extra tips to porters who respectfully salute it. Black would hardly be a suitable colour. A suitable shade of green would be better for the purpose indicated, or some of the art shades or saddle brown, such as are sent to London for less aggressive purchasers. Furniture covering is another use to which they could be put. The small pieces could then be used for pocket-books, tobacco pouches, etc. In all this type of trade it is just a question of introducing a fashion. They advisably should be tanned in this country tastefully with that objective in view. Meantime the War Office frowns on any utilisation of skilled labour for other than military leathers, and while serious development might be begun, it could only be completed on scale after the war is over."

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

MARCH 6.—A. H. PATERSON, Secretary, National Alliance of Employers and Employed, "The Foundation of Industrial Peace." The RIGHT HON. FREDERICK HUTH JACKSON will preside.

MARCH 13.—PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres and other Flemish Cities before and since the War." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The ARCHBISHOP OF CANTERBURY will preside.

MARCH 20.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

APRIL 10.—W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., will preside.

APRIL 17.—PERCY SHUTTLEWOOD, Ministry of Food, "The Food Situation in Germany."

APRIL 24.—MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons."

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

MARCH 14.—WILLIAM FOSTER, C.I.E., "English Commerce with India, 1608-1658."

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India."

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoons, at 4.30 p.m.:—

March 5. — George Young, M.V.O., ex-Secretary of Legation, Lisbon, "Portugal as a Colonial Power." Sir Owen Philipps, K.C.M.G., M.P., will preside.

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

Cantor Lectures.

Monday afternoons, at 4.30 p.m. (unless otherwise announced):—

Edgar Crammond, Secretary of the Liverpool Stock Exchange, "The Effect of the War on the Economic Condition of the United Kingdom." Three Lectures.

Syllabus.

Lecture III.—March 4.—*The Real Cost of the War and the Problem of Economic Reconstruction.* War expenditure of the British Government —War debt — Pensions — Education — Imperial Revenue and expenditure — Excess profits duty —Levy on capital—National debt after the war —Economic reconstruction — Problems of demobilisation—Commercial relations of the United Kingdom with the Empire and our Allies—Interaction of International trade and finance on the economic life of the United Kingdom — The investment of capital abroad.

J. Young, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

Cobb Lectures.

Professor Henry R. Procter, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 4 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. E. Crammond, "The Effect of the War on the Economic Condition of the United Kingdom." (Lecture III.)

Victoria Institute, Central-buildings, Westminster, S.W., 4.30 p.m. Rev. H. J. R. Marston, "The Reserved Rights of God."

Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Professor E. Leflac, "Intensive Agriculture and Catch-cropping in Belgium."

Tuesday, March 5...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Mr. G. Young, "Portugal as a Colonial Power."

Röntgen Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8.15 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir R. T. Glazebrook, "The National Physical Laboratory." (Lecture II.)

Alpine Club, 23, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 8 p.m. Mr. A. Meade, "Modern Developments in Gasworks Construction and Practice."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Mr. R. I. Pocock, "On the External Characters of the Lemurs and *Tarsius*." 2. Sir George F. Hampson, "A Classification of the *Pyralidæ*, Subfamily *Hypsotropinæ*."

Wednesday, March 6 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. A. H. Paterson, "The Foundation of Industrial Peace."

Geological Society, Burlington House, W., 8 p.m.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 8 p.m.

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor S. D. Adshead, "Town-planning in its relation to Public Health."

Royal Archæological Institute, at the Society of Antiquaries, Burlington House, W., 4.30 p.m.

Thursday, March 7...Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Professor E. B. Poulton, (*a*) "The Mimetic and Mendelian Relationships of the 'White Admirals' of North America"; (*b*) "A new Mimetic form of *Pseudacræa poggei* (Dewitz) from ex-German East Africa, with other African mimics of *Danaida chrysippus* (Linn.)." 2. Lord Rothschild, "Mimetic species of the African Nymphaline genus *Pseudacræa* and Lycænid genus *Mimacræa*, together with their Acræine and Danaidine models and some of their co-mimics."

Chemical Society, Burlington House, W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "War Music: Past and Present." (Lecture I.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. R. A. Malby, "Photographic Records of a Miniature Alpine Garden."

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. E. B. Wedmore, "The Control of Large Amounts of Power."

Southern District Association of Gas Engineers and Managers, at the Royal Society of Arts, John-street, Adelphi, W.C., 2 p.m.

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. 1. Mr. H. R. Edmands, "The Application of Charcoal to the Precipitation of Gold from its Solution in Cyanide." 2. Mr. W. R. Schoeller, "Blast Furnace Smelting of Stibnite, with considerations on the Metallurgy of Antimony." 3. Mr. B. Angwin, "A Responsive Shaft Signal Device."

Friday, March 8...Royal Institution, Albemarle-street, W., 5.30 p.m. Professor E. H. Barton, "Vibrations: Mechanical, Musical and Electrical."

Astronomical Society, Burlington House, W., 5 p.m.

University of London, Slade School of Fine Art, University College, Gower-street, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture VIII.)

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, March 9...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Problems in Atomic Structure." (Lecture IV.)

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 1, 1918.

No. 3407. MARCH 8, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society of Arts

CANTOR LECTURES.

A full list of the Cantor Lectures which have been reprinted from the **Journal** and published separately may be obtained on application to

THE SECRETARY, John Street, Adelphi, London, W.C.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

HOWARD AND OTHER LECTURES.

Heavy Oil Engines. Four Lectures. By Captain H. RIALL SANKEY, R.E., M.Inst.C.E. (1912.) Price 1*s.*

Aeronautics. Three Lectures. By Prof. J. E. PETAVEL, D.Sc., F.R.S. (1913.) Price 1*s.*

Surface Combustion. Three Lectures. By Prof. WILLIAM ARTHUR BONE, D.Sc., Ph.D., F.R.S. (1914.) Price 1*s.*

Motor Fuel. Three Lectures. By Prof. VIVIAN B. LEWES, F.I.C., F.C.S. (1915.) Price 1*s.*

Coal and its Economic Utilisation. Three Lectures. By Prof. JOHN S. S. BRAME. (1917.) Price 1*s.*

The Shortage of the Supply of Non-Phosphoric Iron Ore. Two Lectures. By Prof. WILLIAM GEORGE FEARNSIDES, M.A., F.G.S., M.Inst.M.E. (1917.) Price 1*s.*

Journal of the Royal Society of Arts.

No. 3,407. **VOL. LXVI.**

FRIDAY, MARCH 8, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 13th, at 4.30 p.m. (Ordinary Meeting.) PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres and other Flemish Cities before and since the War." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] HIS GRACE THE ARCHBISHOP OF CANTERBURY will preside.

THURSDAY, MARCH 14th, at 4.30 p.m. (Indian Section.) WILLIAM FOSTER, C.I.E., "English Commerce with India, 1608–1658." The RIGHT HON. J. AUSTEN CHAMBERLAIN, M.P., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, March 4th; Mr. HARTLEY WITHERS, Editor of the *Economist*, in the chair. Mr. EDGAR CRAMMOND, Secretary of the Liverpool Stock Exchange, delivered the third and final lecture of his course on "The Effect of the War on the Economic Condition of the United Kingdom."

The lecture was followed by a short discussion, and on the motion of the CHAIRMAN a vote of thanks was accorded to Mr. Crammond for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

COLONIAL SECTION.

Tuesday afternoon, March 5th; SIR OWEN PHILIPPS, K.C.M.G., M.P., in the chair. A paper on "Portugal as a Colonial Power" was read by Mr. GEORGE YOUNG, M.V.O., ex-Secretary of Legation, Lisbon.

The paper and discussion will be published in the *Journal* of March 29th.

THIRTEENTH ORDINARY MEETING.

Wednesday afternoon, March 6th; The RIGHT HON. FREDERICK HUTH JACKSON in the chair. A paper on "The Foundation of Industrial Peace" was read by Mr. A. H. PATERSON, Secretary, National Alliance of Employers and Employed.

The paper and discussion will be published in the *Journal* of April 5th.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s.* each, on application to the Secretary.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1918 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 23rd, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce," and has been awarded as follows in previous years:—

1864, Sir Rowland Hill, K.C.B., F.R.S.
1865, His Imperial Majesty, Napoleon III.
1866, Michael Faraday, D.C.L., F.R.S.
1867, Sir W. Fothergill Cooke and Sir Charles Wheatstone, F.R.S.
1868, Sir Joseph Whitworth, LL.D., F.R.S.
1869, Baron Justus von Liebig.
1870, Vicomte Ferdinand de Lesseps, Hon. G.C.S.I.
1871, Sir Henry Cole, K.C.B.
1872, Sir Henry Bessemer, F.R.S.
1873, Michel Eugène Chevreul.

1874, Sir C. W. Siemens, D.C.L., F.R.S.
1875, Michel Chevalier.
1876, Sir George B. Airy, K.C.B., F.R.S.
1877, Jean Baptiste Dumas.
1878, Sir Wm. G. Armstrong (afterwards Lord Armstrong), C.B., D.C.L., F.R.S.
1879, Sir William Thomson (afterwards Lord Kelvin), O.M., LL.D., D.C.L., F.R.S.
1880, James Prescott Joule, LL.D., D.C.L., F.R.S.
1881, Professor August Wilhelm Hofmann, M.D., LL.D., F.R.S.
1882, Louis Pasteur.
1883, Sir Joseph Dalton Hooker, K.C.S.I., C.B., M.D., D.C.L., LL.D., F.R.S.
1884, Captain James Buchanan Eads.
1885, Sir Henry Doulton.
1886, Samuel Cunliffe Lister (afterwards Lord Masham).
1887, Her Majesty Queen Victoria.
1888, Professor Hermann Louis Helmholtz.
1889, John Percy, LL.D., F.R.S.
1890, Sir William Henry Perkin, F.R.S.
1891, Sir Frederick Abel, Bt., G.C.V.O., K.C.B., D.C.L., D.Sc., F.R.S.
1892, Thomas Alva Edison.
1893, Sir John Bennet Lawes, Bt., F.R.S., and Sir Henry Gilbert, Ph.D., F.R.S.
1894, Sir Joseph (afterwards Lord) Lister, F.R.S.
1895, Sir Isaac Lowthian Bell, Bt., F.R.S.
1896, Professor David Edward Hughes, F.R.S.
1897, George James Symons, F.R.S.
1898, Professor Robert Wilhelm Bunsen, M.D.
1899, Sir William Crookes, O.M., F.R.S.
1900, Henry Wilde, F.R.S.
1901, His Majesty King Edward VII.
1902, Professor Alexander Graham Bell.
1903, Sir Charles Augustus Hartley, K.C.M.G.
1904, Walter Crane.
1905, Lord Rayleigh, O.M., D.C.L., Sc.D., F.R.S.
1906, Sir Joseph Wilson Swan, M.A., D.Sc., F.R.S.
1907, The Earl of Cromer, O.M., G.C.B., G.C.M.G., K.C.S.I., C.I.E.
1908, Sir James Dewar, M.A., D.Sc., LL.D., F.R.S.
1909, Sir Andrew Noble, K.C.B., D.Sc., D.C.L., F.R.S.
1910, Madame Curie.
1911, The Hon. Sir Charles Algernon Parsons, K.C.B., LL.D., D.Sc., F.R.S.
1912, The Right Hon. Lord Strathcona and Mount Royal, G.C.M.G., G.C.V.O., LL.D., D.C.L., F.R.S.
1913, His Majesty King George V.
1914, Chevalier Guglielmo Marconi, G.C.V.O., LL.D., D.Sc.
1915, Sir Joseph John Thomson, O.M., D.Sc., LL.D., F.R.S.
1916, Professor Elias Metchnikoff.
1917, Orville Wright.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, February 14th. 1918; Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I., in the chair.

The Secretary of the Section announced that Lord Islington, who was to have presided, had been obliged to attend a Cabinet Committee Meeting, and, therefore, could not be present. Sir Charles Stuart Bayley had kindly consented, at very short notice, to take the chair.

The paper read was—

THE INDIAN HIDE AND LEATHER TRADE.

By Sir Henry Ledgard,

Late President, Upper India Chamber of Commerce.

I have in the following paper endeavoured to sketch the history and present condition of the hide and leather trade of India, but a few preliminary references to the cattle of other countries may be of interest, and at the same time serve to illustrate the very important position held by India in the leather markets of the world.

Broadly speaking there are but three classes of hides in the world: the heavy hide, yielding the stout, hard, strong leather from which boot soles, machine belting, harness, portmanteaux, etc., are made; the light hide, suitable for the upper leather of Army boots and many descriptions of civilian foot-wear; the sheep and goatskins for light foot-wear, gloves, bags, purses, upholstery, certain textile processes, and the innumerable uses to which thin flexible leather can be put. Of these three classes it may be said that India produces the great bulk of the light hides and skins.

It is, however, rather strange that while the British Empire yields the largest quantity of light hides and skins, the British tanner somewhat neglects them, and in the main devotes himself generally to the tanning of heavy hides drawn from foreign countries, notably the Argentine, South America, Italy, and France. We have also a certain quantity of our own unrivalled heavy "market hides" and imports from South Africa and Australia; but, as I have stated, the English tanner draws the bulk of his supplies of this class from outside the British Empire.

In the Argentine the conditions for the production of a perfect hide are more favourable than in many other parts of the world. The vast

herds of oxen are reared primarily for their meat. They are preserved for that purpose alone; they do no work, and when young and at their best are slaughtered. Contrast these conditions with India, where agriculture is by far the most important industry and the steam plough and motor tractor hardly known. About two-thirds of the 300 millions of population work upon the land, and the chief stock-in-trade of the cultivator are his bullocks. They plough the land, level and harrow it, sow the seed, raise water to the soil from the irrigation wells, tread out the grain, and finally cart the produce to market. For nearly all agricultural work the bullock is a necessity. He works throughout the greater part of the year, and the hard life of toil is often recorded on the hide of the dead animal in sores and scratches, scars or other disfigurements. In the Argentine, branding is practised as a means of identification. In India it is regarded also as a cure of various ailments. I have seen brands or sears aggregating 20 ft. in length, and in one case 40 ft. on one hide. Fortunately Indian cows and female buffaloes are rarely worked; hence their hides are generally in good condition. Neither are cows worked in the Argentine, but their hides are inferior to those of oxen, so we find cow hides may be deemed the better material for making into leather in one country and ox in the other. One other comparison is noticeable. In England, in normal times, the hide of a slaughtered animal may be said to represent about one-twelfth to one-tenth of the total value of the beast. In India, under similar conditions, the hide is worth a third; while on occasion, when cattle-feed is scarce and there is a brisk demand for hides, chiefly from Germany, the animals are slaughtered for the value of their hides alone.

The conditions in India to which I have referred tend to lessen the value of the hides. Nevertheless they produce the most suitable and economical leather in the world for the upper parts of Army boots and strong boots for agricultural labourers, miners, railway and postal employees, etc. The German realised this years ago, and some figures I will give you presently indicate the extent to which he acted upon his knowledge before the war, and, in the opinion of a good many, for a very considerable period after the war.

Our Home Government, however, until recently held a different view as to the uses of the Indian hide, and in their pre-war Army boot contracts barred out East India "kips" in favour of the heavy ox hide. Their inspectors, however, could not always tell the difference in the leather when in the boot, so, in spite of War Office specifications, "kips" were often used, when procurable, to shoe our soldiers. To-day our Government have commandeered these hides in India, are shipping them here, and are begging our English tanners to use them and to build new tanneries and produce all the leather they can for Army boots. Is it too much to hope that they will, before it is too late, go further and take steps to preserve this industry to the British Empire? The Indian hide export trade is not a small one. It ranks fifth in value of the products of India. It actually comes before tea, that magnificent industry of which we hear so much; moreover, are we not all interested in tea nowadays? Why is it that so little is known of the Indian hide trade? It is, as. I think I shall be able to show you later, because the business was to all intents and purposes a German monopoly.

It may be interesting to mention that the total value of Indian exports for the year before the war was £162 millions sterling, and that this amount was very largely made up of what are known as the six chief products of India. These six commodities accounted for £142 millions of the total exports, leaving only twenty millions for the less important articles such as shellac, coffee, gums, rosins, metallic ores, oils, spices, dyes, etc. Now, these six main productions rank in order of importance as follows: (1) Jute, raw and manufactured; (2) cotton, raw and manufactured; (3) food grains; (4) seeds; (5) hides and skins; (6) tea. Further, we should realise that, while over four-fifths of the tea exported finds its market within the British Empire, three-fourths of the hides and skins have been shipped to foreign countries.

How necessary, therefore, it will be in the near future to alter this and "to look after our own" is indicated by the result of a recent investigation undertaken by the American Government. From the *Leather Trades' Review* I learn that in their report serious attention has been called to the shortage the world may have to face in the future as a result of the great increase in meat consumption since the war began. It is estimated that the world's meat-producing animals have decreased in—

Cattle by	28,080,000
Sheep ,, ...	54,500,000
Hogs ,, ...	32,425,000
	115,005,000

Before the war the world's supply of hides and skins was barely equal to the demand, and prices were steadily rising. The figures I have quoted indicate a very serious shortage after the war. What will be our position when all the nations are replenishing their depleted stocks if our Indian resources are again in alien hands?

Hides and Skins in India.

I will now endeavour to confine myself more closely to India and the immediate subject of this paper.

The Statistical Department of India recently published the result of a census of cattle in British India, from which we learn that there were—

Bulls and bullocks	49,000,000
Cows	37,800,000
Young stock	42,900,000
Buffaloes	19,200,000
Goats	33,600,000
Sheep	23,000,000

These figures do not include the Native States, nor are we given the number of sheep in Bengal, or of goats in Madras. Official figures of these are apparently not available, but from the data supplied by the census I think, taking India as a whole, we may conclude that there are in the country 220 millions of cattle including buffaloes, and 80 millions of sheep and goats.

Curing and Preparation.

When an animal is killed, or dies, immediate treatment to preserve the hide is necessary. In the central parts of India, the Bombay Presidency, the United Provinces, the Punjab and Sind, where a dry climate prevails, the hides are usually what is termed arsenicated, *i.e.* they are cleaned of flesh, fat, etc., and sun or shade dried. Before baling for export they are dipped in a bath of arsenic solution and again dried. The arsenic acts as a preservative and prevents insects attacking the hides. This is considered the best method of treatment, as the hides keep well and there are not the opportunities for adulteration or weighting afforded by other cures.

In the damp climate of Bengal, and during the rainy season in other provinces, drying is difficult, so the hides are usually salted. The result is not always satisfactory; often a great deal of flesh and fat is left on the hide to absorb an excessive weight of salt. I have known a dry-salted hide weighing 15 lb., after the soaking in water, dissolving the salt, removing dirt, etc., which when again dried was found to weigh only 9 lb., or a loss of 60 per cent. The purchase of salted hides on a weight basis under these circumstances is not satisfactory. For this reason, in the United Provinces, where dry arsenicated hides are usually sold per 20 lb. weight, hides salted during the monsoon are valued by the piece, after selection and classification.

Classification of Hides and Skins.

For many years the Indian Government purchased large numbers of cattle, kept them where troops were stationed, fed them well for about three months, and then slaughtered them to supply beef to the British soldier. The hides from these, known as "Commissariats," were sold by public tender for a year to three years in advance, and these were the best in India. They were branded on the neck with the letter "C," and a number corresponding with the month when bought, and realised the highest prices. Many years ago the Indian Government discontinued buying cattle, but this term "Commissariat" remains in the trade and indicates the highest grade of hide. The next grade, known as "Slaughtered," signified that the hides were from slaughtered animals as distinguished from those which have died a natural death. The third grade was termed "Deads"; and still lower are "Rejections." These trade terms are still used by the chief hide markets in the central parts of India, the Central Provinces and the Punjab—though the classification has changed. For instance, Commissariat, though non-existent, still represents the best hides, and "Slaughtered" include the next lower grade of slaughtered hides and the best of those from animals that have died. The hides of Bengal, Maherpore, Chittagong and other districts have each their distinctive characteristics and are classified accordingly.

Of goatskins there are in India several varieties. The best are from the Province of Behar and known as "Patnas." They are fine in grain, and ideal for the production of glacé kid skins. Further east, in Dinagepore, Bengal and Eastern Bengal (including Dacca), the skins are somewhat larger and heavier in grain and texture, but still suitable for glacé kid. Passing westward into the United Provinces and Rajputana we find the skins also larger and rather coarser than Patnas, the lighter ones only of value for glacé kid. The heavier are suitable for "Moroccos" for the upholstery trade, but,

unfortunately, many have holes made by the pricks of thorns on trees where the animals feed. Further north in the Punjab the skins are known as "Amritsars." They are large, strong and heavy, and best adapted for upholstery. In the south, Hyderabad and Deccani skins are of fair quality, chiefly purchased by the Madras tanners, and tanned in Southern India.

The Indian Tanning Industry.

Before the war about three millions of cow, ox and calf hides yearly were tanned in India and exported. Since the outbreak of war the enormous and increasing demand for leather for military purposes, both for ourselves and our Allies, has entailed special effort on the part of the tanners in the Madras and Bombay Presidencies, the chief centres of the tanning industry. I think I am right in saying that, with the help of the Indian Government and the efforts of Mr. Wright Henderson, an expert specially sent from home, a splendid result has been obtained, as the present production of Indian tanned ox and cow hides is fully double that of the pre-war outturn. This industry is of such value to India that I trust a further expansion may be seen and the development maintained.

The primary processes, *i.e.* softening, liming, unhairing, fleshing and bating generally, resemble the methods which obtained in England until the introduction of labour-saving machinery. In India, where labour is relatively plentiful and cheap, the Indian tanner still adheres to the more primitive methods.

The tanning material chiefly used in Madras and Bombay is the bark of the *Cassia Auriculata* shrub, commonly known as tarwad. It grows to about 6 to 8 ft. in height, and has no trunk, the shoots breaking out a little above the ground. Shrubs of three to four years' growth are cut and the bark removed. Fresh shoots grow and are again ripe for cutting in about three to four years. Trees are usually destroyed when bark is taken from them for tanning purposes, so in this respect there is a distinct advantage in the use of tarwad.

I know of no tanning material more suitable than tarwad where softness and pliability in the leather are desired.

In the Bombay and Madras Presidencies it is the practice only partially to tan the hides, about half tanned according to our Western ideas; no exception is, however, taken to this as the European currier is able to complete the tanning to suit his requirements, and, perhaps, what is of some importance to him, to add considerably to the weight.

In addition to the Madras and Bombay tanning centres, there are some large and up-to-date tanneries and leather factories at Cawnpore in the United Provinces, well equipped with machinery and under European management. The first was erected over forty years ago by the Indian Government. There, cow and buffalo hides are tanned, curried and manufactured into equipment (other than boots) for the infantry, saddlery for the cavalry, and harness for the artillery and transport. In normal times the entire requirements of these branches of the Army in India are met in this factory. At present, and in addition, enormous quantities are sent abroad.

Later, the firm of Messrs. Cooper, Allen & Co., erected a similar factory for tanning and currying cow and buffalo hides, and the manufacture of boots for British and Indian Armies in India, Egypt and parts of the Far East. The effect of the war has been greatly to increase their operations, and Cawnpore boots are in every part of the world where fighting is going on.

The North-West Tannery is another large and important manufacturing concern devoted to war work.

The tanning materials chiefly used by the Cawnpore tanneries are the *Acacia Arabica* or babul, and *Terminalia Chebula* (the myrabolam nut). For firm leathers babul tannage is very suitable, and can, when toned down with other tanning products, be made to produce excellent upper leather.

There are also smaller tanneries in Cawnpore, and in Agra, Allahabad, Gorakhpur, and Calcutta.

Owing to the great impetus given by the war to tanning, the cutting of tarwad has been very much increased, and I hear there has been a considerable rise in price. In the north, the Cawnpore tanneries have year by year to go further afield in search of babul. Neither of these two tanning agents, so important to the industry, are systematically cultivated. Tarwad is a jungle plant, flourishing in the central parts of India. Babul, a tree scattered over a wide area, chiefly in the northern parts of India, is not ripe for cutting until ten to twelve years old.

Private enterprise will not cultivate the babul tree and wait so many years for a return, nor have I heard of any enterprising Indian tanner taking in hand the plantation cultivation of

tarwad. It is obviously the business of the Indian Forest Department, and I sincerely trust the Government of India will realise the importance of the tanning industry, and assure to it an ample supply of tanning. India can produce the bark, but its exploitation should not be left to private enterprise.

In addition to the tanning centres of Bombay, Madras, and Cawnpore, there still exists, mainly to supply the local needs of the districts, the primitive system commonly known as "country tanning," carried on in the villages. The hides and skins, after the usual preparation, are sewn into a bag, hung up, and filled with water and ground bark. The liquid extract percolates through the hide; twenty-four hours' suspension in the case of cow hides, and forty-eight with buffalo, completes the process. The hides are coloured and look tanned, but a true chemical combination has not taken place. That they are not properly tanned is indicated by the unpleasant smell they give off for a long time. This leather comes to London from time to time in small quantities, where it is known and sold as "stitched hides," or "bag tanned."

Of the three centres of tanning I have reviewed, the Madras and Bombay *Cassia Auriculata* tannage is the largest, and meets an important demand in Europe. The second is a sound tannage, but has a limited market. The third is inferior, only of value where better leather is not available, and will die out as the better tannages find a wider market in India.

Chrome tanning is carried on to a small extent. In this direction there would appear to be great possibilities for India. The adoption of Western attire has led to a considerable increase in the use of boots and shoes of European pattern, and there is no material more suitable for the upper parts of boots and shoes in a hot climate than the soft, flexible leather produced by chrome tannage. Apart from this fact, it is a mineral tannage, and can be extensively developed without adding to the present and increasing demand for the vegetable tanning agents to which I have alluded.

Export Trade.

I now turn to the export trade, which comprises (1) the hides or skins tanned in India, and (2) the raw hides or skins exported and tanned abroad.

Of goatskins, India, previous to the war, exported annually some 20 million pieces in the raw state and 7,500,000 tanned.

The United Kingdom took the greater part of the tanned skins. They were practically all sent to London and disposed of at the public sales held at intervals of one to two months. About half the skins were re-exported to the Continent, and America took about one-third of the remainder.

The handling of the raw skins was on a different footing. America imported direct about 75 per cent., England 10 per cent., France 7 per cent., Holland and Belgium 5 per cent., Germany an insignificant quantity. Since the war America's imports have risen to 88½ per cent., and ours dropped to 8 per cent. or less.

The very large quantities taken by America are turned into glacé kid, and of these England takes annually from America, for her own use, a considerable proportion, valued at £1,500,000.

Of sheepskins the export in the raw state, previous to the war, amounted to 2,200,000, and about 9 millions tanned. Of these raw skins America took in 1913–14, 87 per cent., and in 1915–16, 96½ per cent. In face of these American figures I do not think it necessary to tell you what England imported. The treatment of the tanned skins is rather more favourable. The following are the figures:—

	1913-14.	1915-16.
United Kingdom	58·9 per cent.	64 per cent.
United States	20·9 ,,	19·8 ,,
Japan	15 ,,	11·8 ,,

As with the tanned goatskins, a considerable percentage were re-exported to America and to Austria, and then came back to us in various forms of useful and fancy manufactured articles.

Of buffalo hides about 16,000 cwt., or 160,000 pieces, were exported to England in the tanned state. Unlike sheep and goat skins they were nearly all absorbed in the country. Of the 345,000 cwt. raw hides, representing about two million pieces, the position is fairly summarised when I say that half the number went to the countries now at war with us, one-third to the United States, the remainder to the United Kingdom, Holland, and Italy.

Before referring to the export of ox and cow hides I should state that efforts are being made to increase the manufacture of glacé kid in this country. The chrome tanners have considered the position, and state that they are prepared to extend their factories and deal with an additional five million goatskins per annum, provided Government give them some security for the capital involved. The Tanners' Federation

consider that such security would be provided by an export duty in India on all raw goatskins, with a rebate of the full amount if the skins are tanned within the Empire. The Federation estimate that the value of the increased production in this country would, within three years of the termination of the war, fully equal the cost of the Indian goatskins treated in America and imported into this country in the form of glacé kid, to which I have alluded.

A similar fiscal policy is suggested in regard to sheepskins, and in both goatskins and sheepskins there is a very considerable industry to be created in this country in the manufacture of fancy leather articles, such as bags, purses, etc., a trade hitherto largely in Austrian and German hands.

The Tanners' Federation have also considered buffalo hides, and, in view of the fact that all imported tanned hides have so far been absorbed in this country, express the view that a very much greater number of Indian buffaloes could be handled here if the trade were established with the certainty of supplies in the future.

I now come to ox and cow hides, by far the most important branch of the hide and skin exports of India. Covering a period of some years before the war, the exports have been approximately 11 millions, of which about 3 millions of hides have been exported in the tanned state, and the remaining 8 millions in the raw. Broadly speaking, the tanned hides came to this country, and the 8 million raw hides went to the Continent. At one time, you may be interested to know, all the hides came here, and kip tanning was a most important industry. From the Leeds district alone the outturn was about 3 millions per annum. Kip, I may mention, is the trade term for Indian ox or cow hides.

In 1872 the shipments to the United Kingdom were 7 millions; to other countries none. Ten years later, in 1882, 5 millions came here and 1 million went to the Continent. By 1892 the figures were almost reversed, for 1,038,417 came to this country and 4,423,159 went to the Continent. For about three years longer our imports held up, and we averaged about 1¼ millions against 5 millions to the Continent. In 1896 we dropped to 681,000. Imports continued to dwindle, until in 1913 we imported only 17,530 as against 6,981,947 to the Continent and 261,060 to America.

I have here the details of statistics of exports from Calcutta going back to 1872, but not to weary you with so many figures, I have summarised them in the preceding column.

Shipments of Raw Ox and Cow Hides from Calcutta.

	To the United Kingdom.	To Continent.	To America.	Total.
1872	7,000,000*	Nil.	Nil.	7,000,000
1882	5,000,000*	1,000,000	,,	6,000,000
1887	3,882,443	1,614,363	,,	5,496,806
1888	3,552,956	1,645,880	,,	5,168,836
1889	3,915,367	1,678,485	,,	5,593,852
1890	2,694,554	2,440,315	,,	5,134,869
1891	2,444,148	4,301,734	,,	6,545,882
1892	1,038,417	4,423,159	,,	5,461,576
1893	1,437,317	4,872,637	,,	6,309,954
1894	1,591,011	5,628,416	,,	7,219,427
1895	1,424,719	5,784,802	,,	7,209,521
1896	681,164	5,315,552	,,	5,996,716
1897	700,086	6,181,250	,,	6,882,336
1898	683,266	6,932,099	,,	7,615,365
1899	700,000	6,817,000	335,000	7,852,000
1900†	433,636	9,677,840	464,810	10,576,286
1901	227,748	6,752,912	127,326	7,107,986
1902	90,070	6,035,341	92,340	6,217,751
1903	144,216	6,600,901	97,967	6,843,084
1904	136,794	6,671,278	13,532	6,821,604
1905	174,888	7,719,582	105,007	7,999,577

German Control.

The figures I have quoted show that the trade in raw hides had passed from us when war broke out. What the trade meant to the enemy may best be expressed by indicating what these hides would produce.

The ox and cow hides that went to Hamburg, Bremen, and Trieste in the three and a half years before the war, after making the liberal deduction of 50 per cent. for hides unsuitable for military requirements, yielded sufficient leather to make 48 millions of Army boot

* Estimated.

† In 1900 (the famine year) upwards of 3,000,000 raw hides were shipped from Bombay.

uppers, while the buffalo hides exported to the Continent would supply 49 millions of Army boot soles. Of the remainder, fully half were suitable for making civilian upper leather (of which a large quantity was returned to us in the form of finished box calf), and for making soles for light boots and shoes or the inner soles of heavier boots. How this complete capture of trade has been accomplished is of interest. In 1876-77 the German Government imposed an import duty on leather of 6*s.* 1*d.* per cwt., equivalent to about 6 per cent. *ad valorem.* In 1878 they increased it to 10 per cent. *ad valorem*, and in 1906 the tariff was revised and increased, raising the duties to from $1\frac{5}{8}$*d.* to $2\frac{3}{4}$*d.* per lb. according to the weights of the tanned hides.

Concurrently with these fiscal measures in Germany there arose in Calcutta German firms devoting themselves exclusively to the export hide trade. Before long they had banded themselves into an association or ring almost exclusively German. In case this description of the ring may be questioned, I give you the grounds for my assertion. In 1913 the firms composing this association contained thirty German or Austrian directors, partners or managers, and four naturalised or not German. Of assistants other than Indian clerks, hide sorters, or coolies employed, there were fifty-five German and Austrian and only twelve naturalised or not German. In addition to the association of German hide merchants in Calcutta, a Tanners' Association existed in Germany and a Dealers' Association in Hamburg. The latter worked with the Calcutta ring, and any outsider attempting to do business found himself against the Calcutta association or its counterpart in Hamburg. The Calcutta firms very naturally cultivated intimate relations with their Continental customers, and drew their assistants from Germany or Austria. The hide classifications were made to suit the German tanners. A German line of steamers carried the hides direct from India to the German or Austrian ports. It is true the ring would sell to English tanners or anybody else, but in all essentials it was Germanic in its origin, in its organisation, in its sympathies and ramifications. There was one exception in this co-operative system, and that was in finance, where the German houses apparently found the English banks sufficiently cosmopolitan and wealthy to serve their purpose. If I have wearied you with these details it is from a strong desire that you may understand how completely the trade was dominated by Germany, and realise the very poor outlook if nothing is done to free us from the German incubus. The fight will be short and sharp, and certainly end in a German victory. The Home Government has apparently given more consideration to the subject than the Indian. Possibly the leather shortage over here has been the stimulus. It is not, I think, unfair to say that the Government of India has so far done little with the weapon in their hands in the shape of the "Hostile Foreign Traders' Order." Shortly after the outbreak of war they ordered the liquidation of four German firms out of those comprising the ring, but soon, and, I take it, with the knowledge of Government, other concerns started. How the firms affected regard the changes may, I suggest, be inferred from the following extract from a circular of one of them ordered to be wound up under a Hostile Traders' Order—

"There will be no change in the management, and we trust the new company will receive the same measure of confidence and support hitherto enjoyed by ourselves."

The remaining firms composing the German ring have been allowed to trade, some with, some without, supervision.

Possibly, in the early days of the war, to have entirely shut down the European hide merchants in Calcutta might have caused serious dislocation before new markets had been found and new organisations formed, but that reason no longer exists. The Government are themselves the purchasers, with the aid of British firms, of all the available ox and cow hides, and there is in England and in neutral countries an eager demand for such as are not required by the Government.

In February 1916, with the concurrence of the India Office, an influential and representative committee was formed at the Imperial Institute, including representatives of firms interested in this Indian trade, of tanners in this country, and others qualified to consider the future of the trade in Indian kips.

On July 3rd, 1916, a conference was held at the India Office, under the chairmanship of Lord Islington, which discussed a memorandum prepared by the committee setting forth the ascertained facts of the case. It was then settled that the committee should proceed to ascertain :—

1. Whether British firms would be prepared to take up the raw hide trade in India, and purchase the kips for export.

2. Whether tanners in the United Kingdom would be prepared to take up the tanning of the Indian hides on the large scale required.

The results of the committee's inquiries on these two points were entirely satisfactory, and have been embodied in an important report and recommendations presented to the Secretary of State for India, which so far has not been published. British firms in Calcutta of undoubted reputation informed the committee that they would take up the export trade, and stated their views as to the best methods of securing that in future the East India hide business shall be an all-British industry. At the same time they made it quite clear that their entrance and continuance in the business would be contingent upon the complete removal from the trade of German firms, or firms whose antecedents and connections and membership of the German hide ring set them apart from British firms.

Tanners in this country express their readiness to tan these kips on an increasing scale under certain conditions, the most important of which is that the purchasing trade in India shall be in the hands of entirely British firms free from previous or present German connections.

The United Tanners' Federation of Great Britain and Ireland expressed themselves able to handle increasing quantities up to four millions in the third year after the conclusion of the war, subject to:—

1. The imposition in India of an export duty on raw hides which shall be remitted if they are tanned within the Empire.

2. Confining the export of raw Indian hides to British firms free from any German or Austrian connections. (The term "British firms" is meant to include Indian.)

3. The granting, where necessary and advisable, of financial assistance to tanners, adapting their yards or building tanneries to tan East India hides.

In this report the committee also laid stress upon the importance of the fullest development possible of the tanning of kips in India which shall involve the employment of Indian labour and capital in the manufacture of leather goods from Indian tanned leather. Since the committee's recommendations were submitted, the Government of India have employed only British and Indian firms as their agents in the purchase of hides on the Government account. In the background there are, however, still the old ring firms or their successors resenting their exclusion, agitating for recognition, bringing pressure upon Government, trading with neutrals, and ready to pounce upon the trade (of which they had the monopoly) directly peace is declared and the Continental market re-opens. The Tanners' Federation in this country are under no delusion as to the danger, and recently passed an outspoken resolution to the effect that if "German" firms are included in the buying arrangements in India, and the trade in India is not firmly established in British hands, they will not enlarge their yards and sink capital in order to tan Indian kips.

That is the position to-day of this vast trade. I hope I have succeeded in raising in your minds a desire that it should be retained for the Empire. If I have done so it is incumbent upon me to do more than criticise, and to ask you to bear with me a little longer while I outline a policy that would, I think, give to us at least a measure of that control so long exercised by the enemy.

The Remedy.

In the first place, I urge that no German firm, or firm of German antecedents and connections, shall be permitted to remain in this trade. In precisely defining what I mean, I cannot do better than quote from a speech of Lord Islington on July 18th, 1916, in the House of Lords, when dealing with the case of a German firm in Calcutta that had been engaged in supplying manganese ore to Krupps for the manufacture of steel. He then said—

"The Government of India had long prevented hostile firms carrying on business in India for the benefit of enemy interests; but, for the purpose of determining what was a hostile firm, they were taking as a criterion whether a firm's business was carried on before the war for the benefit of an alien interest and was likely to be resumed on similar lines after the war."

In quoting this admirable definition of a German, or pro-German firm, I must, however, be permitted to say I do not altogether endorse his lordship's statement of what the Government of India have done. I would rather suggest that it is what they may do if sufficient pressure is brought to bear upon them.

Secondly, I recommend that no concern or individual should be permitted to be in this trade in India without a licence, and the conditions attaching to a licence shall be—

(a) That the capital of the licensed company, firm, or individual, shall be entirely British. (The term "British," of course, to include Indian.)

(b) That all partners, directors, or managers of such licensed company or firm shall be British, and without German connection.

(c) That no British subject being under direct or indirect control, financial or otherwise, of foreign interests, shall be allowed to have any share of the capital, or be a partner, director, or manager of such licensed company or firm.

(d) That no license to trade in Indian raw hides shall be granted to a company, firm, or individual who before the war carried on, or was engaged in, the business for the benefit of foreign countries taking part in the war against the Allies.

I may point out that, apart from the main object we have in confining the trade to licensed firms, other advantages are likely to accrue. There would, for instance, probably arise an association not existing for the purpose of maintaining a monopoly, but instead devoted to the development and improvement of the industry in the interests of all concerned, as exists in the tea industry.

Mr. Chadwick, in this room on December 13th, drew attention to the extent to which adulteration is practised in India. The hide trade is not immune, and I have drawn attention to certain malpractices. All the excessive weighting, bad curing, bad flaying, etc., and the evils emanating from them, would all come within the purview of the association, and the remedies besought to improve the quality of the hides would increase their selling value, and if, say, only one shilling per hide were added, I leave it to those with a taste for figures to estimate the sum that would reach the pockets of the cattle-breeders and hide-sellers of India.

Thirdly, a careful consideration of the fiscal policy outlined by the Tanners' Federation as essential to the revival of the light leather tanning industry in England and its expansion in India.

There is nothing revolutionary or impracticable in these proposals. They are, in their main features, already embodied in the Non-Ferrous Metal Bill, which has met with general approval and received Parliamentary sanction as a measure of protection in the best sense of the word.

Finally (and in this I have in mind the trade of India as a whole), there should be closer commercial union, some preference or privilege—call it what you will—that will render us more self-supporting and self-contained, more independent, and, let me add, more alive to enemy machinations than we have been in the past.

DISCUSSION.

The Chairman (Sir Charles S. Bayley) said the paper formed a very valuable contribution to the knowledge at present existing of one of the leading Indian trades, of its growth in the past and of its possibilities of future development. The subject naturally divided itself into two branches—the tanning trade and the export trade in raw hides. The author had shown the importance of the tanning trade by the various figures he had given in the paper, and to that information he would only add that he had been informed that Indian tanned hides were now providing some 60 per cent. of the material required for the upper leathers of Army boots. The subject was one that had claimed the special attention of the Indian Munitions Board, whose vigorous action in controlling the industry could not fail to stimulate tanning in India, and would probably do much to improve the methods at present employed, of which the author had given such an interesting account. The question might have occurred to some whether there were sufficient hides in India to supply both the tanning and the export trade. The author had stated that the recent census of cattle in India showed that in British India alone there were something like 220,000,000 cattle, which proved that for the present at any rate there was an ample supply of hides, and he did not think that there need be any apprehension whatever about the future. England and India were both vitally interested in the tanning trade, and should do all they could to encourage it. Equally they must wish success to the raw hide export trade, and to the endeavours which were now being made to divert that trade to British tanneries. The author had shown that for many years past the raw hides had been finding their way to Germany in increasing numbers, and certainly the position was a very remarkable one. In the year 1887, about 70 per cent. of the raw hides of India were exported to England, but in the year 1913, the year before the war started, the proportion was ·02 per cent. He did not know why it was that the English firms had allowed so valuable a trade to pass out of their hands: the fact remained that it had gone, and it was of the utmost importance that the circumstances to which the war had given rise should be used to revive it, if possible. The Government of India had given their fullest consideration to the matter, and had taken exceedingly drastic steps to purge the firms engaged in the trade from enemy influences. The matter, however, was a very difficult one, and there were obviously considerable opportunities for differences of opinion as to the further steps which should be taken. The individual cases mentioned by the author were under consideration, and were no doubt being dealt with as well as possible. The author had advocated certain concessions to the trade, and he was quite justified in doing so. The concessions might or might not be expedient in themselves, but it was certainly very desirable that the whole matter should be fully ventilated and discussed.

He could not help thinking that anyone who had listened carefully to the paper must see that the concessions suggested would involve very big consequences indeed, and that they also involved the application of certain principles which could not be confined to any single trade. For example, the suggestion that an export duty should be imposed on raw hides shipped from India, and that a rebate should be allowed if the hides were tanned within the Empire, might be a most excellent thing, but there was no doubt that other trades would apply for a similar concession, and it was a matter of high policy whether a general application of that principle would be a good thing or whether it would in any way interfere with the export of raw produce from India in the hide and other trades. That was a point that required careful consideration. Then again, the author had suggested that the export hide trade should be confined to firms of purely British origin, and had quoted, in support of that view, a speech made by Lord Islington in 1916. It must be remembered, however, that Lord Islington delivered that speech two years ago, and perhaps he would not say exactly the same thing now. The position had wholly altered during the last two years. In 1916 America had not come into the war; now she was fighting by our side, and the question arose whether we were to treat American firms in precisely the same way as German firms. He thought that if Lord Islington were speaking at the present time he would probably substitute the word "enemy" for the word "alien" in the passage quoted by the author. That, again, was a question of high politics that had to be very carefully considered. All were absolutely agreed as to the great importance of eliminating enemy interests of every kind, and he felt certain that the Government of India would take every step it could with that object in view; but the question of the elimination of all alien firms was a very large one, and one which he at any rate could not discuss at the present time. Everyone would unite in hoping that any conclusions at which the Government of India and His Majesty's Government might arrive would be framed in the best interests of India, of the whole Empire, and of the great industries amongst which the hide and leather trade must certainly be included. It was to be hoped that the present war, with all its disastrous results, would at any rate help to draw the Empire together, and make it self-supporting and encourage and forward its trades in every way.

Mr. H. Percy Densham (Chairman of the United Tanners' Federation) said the author had mentioned the views expressed by the Tanners' Federation on many points, and since those views were first put forward the trade had progressed still further, and was already producing leather satisfactorily from the East India kip. If the requisite protection, not necessarily in the way of duties, could be obtained, the Federation intended to build up that trade. The chief protection it asked for was that the handling of the raw material should be entirely in the hands of British firms; without that protection the trade could not be increased. A great deal had been said about the value of the East India kip for Army boots. If this war proved to be the last war, as everyone hoped it would, the leather made from the East India kip would still be very valuable for the civilian trade. The suggestion had been put forward in the paper of an export duty on raw hides shipped from India, with a rebate to users in the Empire, and the Chairman had expressed a doubt whether that would be advisable, seeing that the United States had now joined the Allies. While agreeing that it might be right that our Allies should receive consideration, he thought the first thing we ought to look forward to for the reconstitution of the Empire was the conservation of our raw materials primarily for the people of the Empire, and we had a perfect right to ask for some such consideration. The author had pointed out that the number of live cattle in the world had been seriously reduced, and that there would probably be a shortage of hides. Further than that the consumption of leather owing to the war had enormously increased, and, therefore, there was bound to be a shortage of leather. India was one of the greatest raw material producers in the world, and it was very desirable that that raw material should be conserved for use in the Empire. Perhaps rather more weight had been given to the question of the East India kip than to that of goatskin, but he was glad to be able to report that the glacé kid manufacturers of this country were prepared to go ahead to an enormous extent if a reasonable amount of protection and perhaps financial assistance were given to them by the Government. It seemed absurd that 75 per cent. of the 20,000,000 goatskins produced in India should go to the United States, and that this country should then take from America a large proportion of the glacé kid produced from that material, when the process could quite well be carried on in this country. With regard to buffalo hides, they were useful for many purposes. They were absolutely essential for the making of pickers and buffers for the cotton and woollen trade, and they could be tanned into a sole leather, either by the vegetable or by the mineral process, suitable for wear in dry and sandy climates. The leather producers of this country were prepared to take the matter up seriously, and greatly increase their consumption of that material. They were also anxious that the resources of India herself should be developed; they were not asking to have the raw material at the expense of the Indian Empire. They wanted India to manufacture or semi-manufacture the leather as far as possible, and then they wanted any surplus raw material there might be to come to them. With regard to the vegetable-tanned goatskin, that was absolutely essential for the fancy leather trade, there being no skin in the world which was so adaptable for the manufacture of all classes of

fancy goods. Unfortunately, that trade in the past had been largely in the hands of the Germans, but during the war successful efforts had been made to increase the trade in this country. The war had proved the value of woman labour in that industry, as in others, and woman labour was going to enable this country in the near future to compete freely with the cheaper productions of other countries, and to meet the home demand for fancy leather goods by the products of our own labour.

SIR J. D. REES, M.P., said the issue arising out of the paper was whether the important trade with which it dealt had been released from the German domination under which it had fallen, and, if so, to what extent it had been released. Had those shackles been removed so that the Germans would not be able to take possession of the trade again after the war? He had been personally much interested in the subject, and had asked questions in Parliament as to what was being done about it. The Government of India had placed the matter in the hands of a committee consisting of merchants who had no German taint about them, but there was a feeling now that the Government had somewhat faltered upon its path, and he would like to feel certain that the Government of India and the India Office were determined to rescue the trade from the hands of the Germans. It was a very serious matter that, whereas in 1872, 7,000,000 hides were imported into the United Kingdom from India, in 1915 those importations had decreased to 408,000, and 4,000.000 hides went to the Continent, chiefly to Germany. If the recommendations contained in the paper were carried out, a great deal could be done to foster the cause of British trade in India, which he was old-fashioned enough to think ought to be chiefly in British hands.

SIR EDWARD PENTON, K.B.E., Royal Army Clothing Department (Boots), said this country owed a great debt of gratitude to the author for his untiring energy, his wise advice, and the great help that he had rendered to the War Office since the beginning of the war in regard to the supply of Army boots and the provision of leather. There was no man in the Empire who had a wider experience of leather equipment for the Army than the author, and when the War Office embarked on a very much more extensive use of the East India kip he gave very full information, which enabled them to work with that particular leather satisfactorily. When the war began the Government had two patterns of boots, one made from a British market hide, known as shoe butt, the other from a fully chrome-tanned hide. At that time the upper leather industry of this country was not adequate to supply the amount of upper leather required, and a very large quantity had to be imported; but when, later on, it was decided to use in very large quantities the East India tanned kip, this country made itself self-supporting as far as the leather required for Army boots was concerned, and it also supplied leather for the boots of a good many of the Allies' troops. The East India kip had been probably more serviceable to this country as a vegetable tannage, because the bulk of the hides were comparatively light, at any rate as compared with the British market hide. Great Britain owed a considerable debt of gratitude to the Indian Empire for the hides, both tanned and raw, that it had supplied, without which we should not have been able to do all that we had done as regards the booting of our own Army and that of our Allies. He agreed with the Chairman that about 60 per cent. of the material required for the British Army boots was obtained from Indian tanned hides. If the members of the tanning trade and of the leather trade generally who were present would go away from the meeting with a determination to do a little self-examination as to why the trade had been lost to such a great extent, he thought the paper would have done a great deal of good. It was probable that the trade had been lost through lack of imagination; there was no doubt that British traders did lack imagination, and very often allowed a trade to slip out of their hands because they could not project their minds into the future and see what would be the result of a certain process. His own view was that the tanning trade slipped out of our hands with the introduction of chrome tanning, when the average British tanner thought he could do a little chrome tanning in an odd corner, whereas the Germans adopted the process on a large scale.

MR. CECIL J. LONGCROFT (Messrs. David Sassoon & Co., Ltd.) thought that the hide and leather trade illustrated what had happened in many other trades. The people of this country had not recognised that in dealing with a trade it was necessary to analyse it and see whether it was of a character that was desirable for the Empire. They had been contented with aggregates of figures and had neglected the making of a careful analysis. As in the case of other trades, this country had allowed the leather trade to pass into the hands of aliens, and had bought cheapness at too dear a price. We had been too much inclined to buy German leather at the very cheapest price, when, with a little more enterprise, we might have produced the leather ourselves. With regard to the export trade, it was undoubtedly in the hands of German firms when the war broke out; the Government found that out because they had either to liquidate or licence all the firms in the trade. He thought they ought to have taken their courage in both hands and closed down all enemy firms, thereby giving to the British firms who proposed to start an opportunity to acquire the organisation and the labour that had been in the trade. By reason of the hesitancy of Government, those firms that entered the trade had never felt secure of their position. If a purely British firm were asked to enter the trade they

said, "We have no confidence in the Government: we do not believe that the Government intend to do what they say they will do." A buying committee was set up by the Government in Calcutta, but it had only been in existence for about three or four months when the Government proposed to take action to close it down, It had apparently carried on its work satisfactorily; no charge of incompetence had been made against it, and it imagined that its existence might be prolonged considerably. The committee felt that at the present time it was in a state of suspended animation, because the officials of the Government had not yet declared what their policy would be in relation to the trade. It was very difficult to trace the reasons actuating the Government in adopting their present attitude towards the trade, and especially in their attitude towards purely British firms who had entered the trade for the express purpose of making good the deficiencies produced by the liquidation of enemy firms. Unless that question was approached rather from the standpoint of commercial interests than of official interests the trade would not make the advance it might otherwise do. There had not been a single case in which the Government had had to complain of the shipments of British firms. There had been a reasonable expansion in the trade, but further expansion would be very much hindered unless the Government made up its mind finally to extirpate all German influences. When once a trade passed into British hands it was dealt with in a broad fashion. For example, whilst the Germans were carrying on the trade very little was done in the way of reform, but as soon as British firms entered the trade and got into touch with the Government expert, Mr. Wright Henderson, two or three reforms were introduced at once. First of all, there was an abolition of the unduly complicated classifications of the Germans, who had two or three hundred classifications; and, secondly, at the instance of the Government a scheme had been introduced by which the branding of the cattle could be conducted on much better lines. British traders were not necessarily narrow, as some people supposed, and at least two firms had entered the tanning trade in India with the object of developing that trade in the interests of India. If the Government would take its courage in both hands and see that the trade was confined to purely British firms, they would have no reason to regret it. On the one hand the tanner would be sure of his raw materials, and on the other hand the Government would know that if, in the event of another war, they required a large quantity of leather, they would not be so entirely at the mercy of the German element as they were when the present war broke out.

On the motion of Mr. S. B. Leigh Taylor, seconded by General Sir Edmund G. Barrow, G.C.B., G.C.S.I., thanks were accorded to Sir Henry Ledgard for his valuable paper, and the meeting terminated.

WATER-SUPPLY FOR IRRIGATION AND POWER IN SOUTH-EASTERN AUSTRALIA.

Australia will, sooner or later, be bound to receive emigration on a great scale from this country, and also to absorb the surplus of some of the 360,000 soldiers which she has sent to the war. Hence the extra settlement on the land after the war is concluded is most essential.

The country referred to in this article may be divided into two regions—that moderately supplied with rain, and the arid portion, the former being chiefly adjacent to the coastline and of undulating character, rising in many parts to the magnitude of mountains. The comparatively arid interior, which is the larger in area and fairly level in feature, is for the most part given over to sheep and cattle, whereas the upper country is at present more or less cultivated by tillage. The rainfall in these flat districts is light, but also particularly rich in plant food; the only thing wanting is water. The water must be gentle in its application, like that of light rainfall, so that it may not wash away the soluble constituents of the ground into the rivers, thus retaining them in the soil. The conclusion is plain. The water must come from hills to the plains, by gravitation or pumping, preferably by the former, as the latter is expensive. It should be borne in mind that the supply must be very ample, in order to compensate for the evaporation which takes place in marshes and lagoons under the fierce sun of the interior, to the extent of nearly half an inch daily. So great is this evaporation, that, contrary to the ordinary nature of rivers, in this case the streams contract as they flow down to their outfall, the opening of many road and railway bridges, in accordance with this peculiar feature, being decreased as the river's mouth is approached.

Dr. Johnson's remark as to the possibilities of a Scotchman is applicable, in a special sense, to the youth and the training of such rivers as these, which may be caught by dams while still in the mountains, thus preserving their valuable flowing waters for irrigation, which would otherwise run to waste.

The most important irrigation scheme yet undertaken, and now almost complete, is the damming of the Murrumbidgee River at Burronjuck, New South Wales, the description of which was given in our columns in the summer of 1913. As that is over four years ago, the chief features may now be briefly recalled. The storage dam is of concrete of gravity section, 240 ft. high, the river affording a channel 220 miles long, which gives access to the rich chocolate, but semi-arid, lands beyond, the intervening district needing no irrigation, as it is plentifully watered. The height of the dam is considerable, and therefore very suitable for a power scheme. This may be utilised elsewhere as a gravitation project in South-Eastern Australia, when joy bells are ringing and joy cars are running for peace and plenty. The work has been much

delayed by the war, owing to the diversion of labour and the raising of the Australian contingent of 360,000 men, but it has now been, fortunately, almost finished, otherwise the concurrent expenditure on the fighting must have been difficult to meet.

The storage reservoirs on the upper Goulburn River in Victoria are the only works at present in operation as a gravitation undertaking which permits of power facilities.

The first settlement of the pumping station of Mildura, Victoria, for irrigation purposes from the Murray River, was carried out in 1884. The area of the settlement is 45,000 acres, of which over 12,000 acres are under intensive culture, principally fruit.

The Ronnark Irrigation Trust, South Australia, is also pumped from the Murray. The district served is 5,270 acres.

The main irrigation works in Queensland are as follows: Those at Ayr, which utilise the waters of the Burdekin River; those at Bingera, near Bundaberg, which utilise water pumped from the Burnett River; and those at Fairymead, which utilise water pumped from a number of shallow spear wells sunk on the alluvial flats on the north side of the Burnett River, and about six miles from Bundaberg. There were in all 11,000 acres for irrigation.

The projects in contemplation are numerous, and only await realisation when immigration is to the fore and available funds are in hand. They are altogether in the State of New South Wales, and are as follows:—

Darling River, of which a preliminary investigation has been made. Lakes Boolabooka, Ratcatcers, and Victoria, and a number of other lakes fed from the river in high floods from the Talywalka Creek, which takes off from the river about 260 miles above Menindie, are available for irrigation.

Lachlan River is also to be made the site of a storage reservoir at Wyangala.

The construction of a storage reservoir serving the Macquarie River, at Burrendong, for the purposes of irrigation by gravitation, is also proposed.

Hunter River: a scheme has been prepared for providing water by means of pumping from the river, the valleys of which are the most fertile districts in the State, and are capable of carrying a dense population under the conditions of intensive culture by irrigation.

Naomi and Peel Rivers: surveys have been completed for storage dams on the Peel River, near Bowling Alley, and the Namoi above Manilla.

The Warragamba River project will serve the dual purposes of amplifying the Sydney water-supply, and irrigating the best lands in the Hawkesbury Valley. It is proposed to construct a large storage dam, capable of supplying at least 80 million gallons daily for domestic service, 30 million gallons daily for trade purposes, and 80 million gallons daily for irrigation.

The water from the artesian area, which is included in the district referred to above, is not sufficient for agriculture; it only serves to supply sheep and cattle.

ECONOMIC VALUE OF GRASS TREES.

The economic value of grass trees has formed a subject of investigation in South Australia, and as a result an interesting treatise has been issued by the Department of Chemistry in that State. Attention was drawn to the matter (says the Sydney *Morning Herald*) on account of the fact that the resin known as yacka gum appears likely to be of considerable commercial importance in the future. Among the many interesting facts mentioned by Mr. J. C. Earl, the officer of the department who was entrusted with the work of investigation, is that grass trees are not found outside Australia, and that therefore their study is a peculiarly Australian problem. They yield products the like of which are not obtained from other plants. On account of their slow growth there is little danger of any industry built up on their systematic exploitation being filched from Australia, as in the case of the eucalyptus oil industry, by the establishment of plantations in other countries. There appears to be some likelihood, however, that by the time this national asset is fully established the trees will have been practically exterminated in many places by careless destruction. Large numbers of these stunted growths, for instance, were destroyed in the clearing of the land for soldiers' homes at French's Forest.

The only product at present of commercial importance is the resin, variously known as gum acaroides, yacka gum, and grass-tree gum. Previous to the present war, by far the larger part of the output of resin gum was consumed by Germany. The purposes for which it was used are not known with any certainty. Inquiries made in 1910 led to the explanation that it was used chiefly in Germany for colouring wine. It is difficult to justify this explanation practically, as the resin is not soluble in dilute alcohol of the strength of wines. More recent inquiries indicated that the main use in Germany of the resin was in the manufacture of cheap furniture polish and lacquer for metalware. It is not certain, however, that other uses of which we are not yet aware were not found for it. Resin derived from a species of grass tree was one of the earliest known sources of picric acid, a yield of 50 per cent. of which was said to have been obtained by treating the resin with strong nitric acid. As picric acid is one of the most widely used of modern war explosives, and was also used formerly to some extent as a dyestuff, an impression has arisen that the resin was being used for picric acid manufacture. Whether this was so or not it is impossible to say, but experiments seem to indicate that as a

raw material for picric acid the resin would hardly be a commercial success, in view of the abundance of more suitable materials. Dissolved in methylated spirit the resin gives a spirit varnish of a deep orange-red colour, and it is also said to find considerable application in England in the manufacture of linoleum. The core and leaves of the grass tree are further believed to be useful in the production of pulp for paper-making, though it is found somewhat difficult to bleach.

INCREASED USE OF CUNAO OR CHINESE GAMBIER.

There was an increased trade in cunao or Chinese gambier in South China during 1916; the volume of the trade in this product in Hong-Kong alone is nearly 30,000 short tons (of 2,000 lb.) annually. The product is one of great value, and merits the attention of dyers. It has been used by the Chinese for many generations for dye and preservative purposes, and, since the disappearance of aniline dyes from the Chinese market as a result of the war, it is coming into still more general use. The dye is the product of crushing and soaking the root of a plant known by the Chinese as "cunao," and drawing off and concentrating the liquor therefrom.

According to a report by the United States Consul-General in Hong-Kong, there are two qualities of the product reaching the Hong-Kong market for Canton and other ports, one of which is the product of Kwangsi and Yünnan Provinces, coming largely from Lungchow and Luk Po in Kwangsi, and from Mengtse and Yünnan-fu in Yünnan Province. It is obtained in large quantities and good quality from the hills bordering the Red River in Yünnan and Kwangsi Provinces. The other quality is the product of Indo-China and certain other parts of Yünnan Province. Usually the Indo-Chinese product is employed for the first dyeing of a cloth or for the coarser work in other lines, while the Chinese product is used for the second or finishing dye, because of the deep, rich brown gloss it gives cloth.

The dye is of a brown colour, is highly astringent, works well with various mordants, and is used extensively by the Chinese for dyeing both silk and cotton, a certain class of silk dyed with it being one of the standard cloths of South China. The coarser quality is also the chief component part of a mixture applied to fishing-nets, sails, and similar fabrics to prevent rot. The product seems to have all the merits of gambier, and in general is much cheaper.

It is handled in China and in the export trade to near-by countries as a paste, and is said to lose its finer qualities if kept too long. Apparently, however, there is no reason why the product cannot be further concentrated, and, if properly packed, ought to keep indefinitely. In its moist condition, as sold in the Hong-Kong markets, it costs about 1*d.* per lb., although at times recently the price has advanced to as much as 1½*d.* per lb. With more modern treatment of the product itself, and with more scientific packing than is usually given it by the Chinese, there seems no reason why it should not be successfully introduced into other countries.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Nettle-fibre.—A collection of the available published accounts makes the prospects of the nettle-fibre industry none too brilliant. First it is needful to get one's stinging nettles and plant them out singly, and both the planting and harvesting require labour at the same time as do the more valuable crops. When harvested there is a yield from wild nettles of about 10, and from cultivated nettles of up to 30 per cent. of bast fibre. The fibre is prepared, according to a Vienna method, by first steeping and then roasting the stems, when a fibre suitable for cordage and jute-spinning is recovered. Upon a Danish system the nettles are cut and stacked for the winter, their tops and leaves are removed, and retting is done either in a pond or in four days' immersion in hot water. The stalks are dried, broken, scutched and hackled, and by this system also a cordage and sacking fibre has been obtained. Promises of better results are held forth, but as to these there is no need to be too sanguine. Better results can, doubtless, be got also from plants which are no more difficult to raise and decidedly easier to work. If one were to reason from the analogy of ramie (or stingless nettle) there are probably a score of points upon which reassurance would be sought before accepting the success of the stinging nettle as granted. As all textile fabrics in enemy use are collected from the battlefields and subjected to examination in British laboratories, the conspicuous success of any new improvisation would soon make itself known. Nettle-fibre sand-bags and cap and coat linings have been identified, and use of the article in shirts and towels is at least suspected.

Intellectual Status.—It would be interesting to know precisely what the Departmental Committee on Textile Trades had in mind in suggesting that "staffs of British firms often occupy a lower intellectual place than their foreign competitors." To deal first with the facts, it is scarcely to be disputed that the rank-and-file of the mill are drawn from the least educated section of the surrounding community, and no very high education is needed to make one tower above the rest, and so qualify for what can be called a staff appointment. In the offices and warehouses of the trade no distinctly intellectual endowment is demanded, and when found there is not necessarily rewarded more highly than in other commercial quarters, where energy is the quality in most demand. It would be highly ungracious not to

allow for these exceptions which stultify generalisations based upon averages, but it can doubtless be maintained that, whether in the industry or the trades, no great intellectual standing is required to cause one to emerge from the ruck. If this be so, what is the reason? According to the Committee, the apathy of individual employers about the advantages of a highly specialised education. An alternative and not less available explanation would be the failure to require all-round a fuller degree of general education. Some progress has been made towards making the textile trade a career for well-educated men, and it may be believed that the work will tend to grow more interesting to them as time passes, and as new learning is applied to it. There are, for example, individuals who have thought it much more interesting to be an engineer, dealing with varied problems, than to settle down to manufacturers' routine.

Water Power.—If further instances were wanted to illustrate the influence of water power in determining the distribution of textile industry, some few might be added to the citations in Mr. Alexander Newlands' paper to the Society. Arkwright, after a beginning in Nottingham, set up his water-frame machines at Cromford to take advantage of the swifter river. "The able stream with a constant supply of water" led the Lombes to Derby, where the forerunner of all English textile factories was founded. The water was wanted in these cases for power, but not less essential to textile industry is water for washing, and it is manifest that the quantity and quality of water available for scouring, dyeing and bleaching have had great influence in the choice of sites. The water-wheel, as a source of power, is extant in remote textile districts, notably in Wales and in the Isle of Man. A water turbine in the Wharfe drives one of the most considerable worsted mills. Remains of water-driven mills are encountered in the West Riding valleys, from which, however, many have made a remarkably clean disappearance. Men not absolutely old recall in one short and pretty valley six wheels, of which no vestige can be found to-day. The historical evidence hardly supports Mr. Pratt in his supposition that British textile industry began upon the eastern edge of England, or that it was originally established by refugees. There was, however, about a hundred years ago, a notable transference of the worsted industry from East Anglia to Yorkshire. The occurrence coincided with the advent of spinning machines, which were driven principally by water-power. The new industrial North knocked Norwich and its cumbersome methods quickly out of competition.

Raw Supplies.—A more acute anxiety in finding tonnage now threatens the peace of mind of textile exporters. It is worth observing that the value of exported textile manufactures last year was approximately £17½ millions, or more than 50 per cent. higher than the £11 millions of 1915. The increase is, of course, one of prices, and when a comparison is made of the quantities of raw materials imported in the same years the facts of the position are more apparent. Of raw cotton the imports of 1917 were 51 per cent. of those of 1915; of wool 67 per cent.; of flax, hemp, and jute 50 per cent.; and of silk 87 per cent. It can be added that there are prospects of further decrease, inconvenient as it must be, and reluctant as some traders are to admit the necessity. As in the depletion of the labour supply, so in the curtailment of import and export trading the difficulties grow in complexity the further the inroads are driven. All manufacturers have not had the opportunity of sheltering under the Government umbrella, but those who have exercised an option to take Government work in preference to private orders can hardly be regretting their decision.

OBITUARY.

THOMAS TYRER.—Mr. Thomas Tyrer died suddenly on February 20th, at the age of seventy-five. He was educated at the Royal College of Science, and in 1862 was appointed works chemist to Messrs. May and Baker, manufacturers of fine chemicals, subsequently becoming managing director of the firm. For the past eighteen years he controlled the well-known works at Stratford which bear his name. Mr. Tyrer was very closely associated with the Society of Chemical Industry, and served on its council during the greater part of its existence. He was on the governing board, and on the executive, of the National Physical Laboratory, and a member of the council of the Association of British Chemical Manufacturers. He was also one of the first members of the old London School Board. He took a very active part in the efforts to secure relief from the duty on alcohol for use in arts and manufactures, and in 1904 he read a paper on this subject before the Royal Society of Arts, for which he received a silver medal. He was elected a Fellow of the Society in 1914.

GENERAL NOTES.

BRITISH FLAX.—The President of the Board of Trade has appointed a Committee "to investigate in all its bearings the question of increasing the supply of flax in the British Empire." The Chairman of the Committee is Lord Colwyn (formerly Sir Frederick Henry Smith, Bt., indiarubber and cotton manufacturer), and the Vice-Chairman Sir Frank Warner, K.B.E. (President of the Silk Association and a member of the Council of the Royal Society of Arts). The other members of the Committee are Sir Thomas Mackenzie, K.C.M.G., and Messrs. W. N. Bease, J. R. Campbell, R. G.

Campbell, Andrew Fisher, W. L. Griffith, P. C. Lyon, C.S.I., T. H. Middleton, C.B., J. R. W. Robinson, and E. F. L. Winter. The Secretary of the Committee is Mr. John A. Todd, B.L., Professor of Economics, University College, Nottingham, who, it will be remembered, read a valuable paper before the Indian Section of the Society last session on "The World's Cotton Supply and India's Share in it." The address of the Committee is Gwydyr House, Whitehall, S.W. (1)

Henry Saxon Snell Prize.—The Henry Saxon Snell Prize, which was founded to encourage improvements in the construction or adaptation of sanitary appliances, will be awarded by the Council of the Royal Sanitary Institute in 1918. It will consist of fifty guineas and the medal of the Institute, and is offered for an essay on "Suggestions for Improvements in Apparatus and Appliances for Dealing with House Refuse." Particulars of the competition may be obtained from the Secretary of the Institute, 90, Buckingham Palace Road, S.W. (1)

East African Beeswax.—Beeswax has recently formed an important article of export from East Africa, the latest market quotations putting it at £8 15*s*. to £9 15*s*. per ton. Apiculture is, however, an industry which has been much neglected, says *South Africa*, being confined to the European settlers on the high lands, a part of the country most suitably adapted for the industry. There are two rainy seasons, no winters, and very little sickness among the bees. Encouragement is being given by the Government to those who have a fancy for apiculture, and it is believed that in the near future the industry will be substantially developed. At the present time the gathering of the beeswax is almost entirely in the hands of the natives.

Rumanian Petroleum.—It was recently stated by a German authority on oil that the fuel value of Rumanian petroleum is very high, viz., 11,000 calories per kilogramme, as against 8,000 for the best Welsh coal. Germany has hitherto obtained oil from Austria-Hungary, which in 1913 produced well over 1,000,000 tons of the crude product. The *Motor* suggests that Germany anticipates an enormous development of the Diesel engine, and it may be expected that Germany will get hold of all the oil sources she can, so as to be independent of coaling-stations. An 8,000-ton ship with Diesel engines can make the trips to Japan and back on 700 tons only.

Liquid Fuel in the War.—Liquid fuel is used now for the forging of shells in the chemical industries, and, owing to the air raids and the danger involved when coal is used, works of special importance to the Government are equipped to burn by-products, such as tar, creosote, and other liquid fuels that, prior to the war, had no special value, and claimed no proper attention from the producers.—*The Shipping World.*

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

March 13.—Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, "Ypres and other Flemish Cities before and since the War." [The paper, which will be given in English, will be illustrated by numerous lantern-slides from unpublished official photographs.] The Archbishop of Canterbury will preside.

March 20.—Percy Shuttlewood, Ministry of Food, "The Food Situation in Germany."

April 10.—W. Lawrence Balls, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." Professor William Bateson, D.Sc., F.R.S., will preside.

April 17.—Frank Stuart Courtney, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." Sir John Snell, M.Inst.C.E., will preside.

April 24.—Major Sir Robert Armstrong Jones, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons." The Right Hon. Lord Sydenham, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

May 1.—George Martineau, C.B., "Sugar from several Points of View."

May 8.—John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

May 15.—Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

May 29.—Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." Sir William A. Tilden, D.Sc., LL.D., F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m.:—

March 14.—William Foster, C.I.E., "English Commerce with India, 1608–1658." The Right Hon. J. Austen Chamberlain, M.P., will preside.

April 18.—Alfred Dickinson, M.Inst.C.E., "Water Power in India."

May 30.—Hon. Sir Dinshaw E. Wacha, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoon, at 4.30 p.m.:—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana."

Cantor Lectures.

Monday evenings, at 8 p.m.:—

J. Young, A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22. At 8 p.m.

Cobb Lectures.

Professor Henry R. Procter, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

Monday, March 11...Brewing, Institute of (London Section), at the Imperial Hotel, Russell-square, W.C., 7.30 p.m. Drs. Arthur Harden and S. S. Zilva, "The Anti-Beri-beri and Anti-Scurvy Accessory Substances in Beer."

Geographical Society, Burlington-gardens, W., 8.30 p.m. Mr. R. Farrer, "My Second Year's Journey in Kansu."

Electrical Engineers, Institution of (Western Local Section), Merchant Venturers' Technical College, Bristol, 5 p.m. Mr. E. B. Wedmore, "The Control of Large Amounts of Power."

Tuesday, March 12...Sociological Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. The Right Hon. J. M. Robertson, M.P., "The Idea of Race Psychology."

British Decorators, Institute of, Painters' Hall, Little Trinity-lane, E.C., 6.30 p.m. Mr. F. Dakin, "The Decoration of a Town House."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Professor D. S. Margoliouth, "Some Sources of the Arabian Nights."

Royal Institution, Albemarle-street, W., 3 p.m. Dr. L. Hill, "The Stifling of Children's Health." (Lecture I.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Professor J. C. McLellan, "Exhibition of Cinematograph Films illustrating Water-power Works in Canada."

Anthropological Institute, 50, Great Russell-street, W.C. (Joint Meeting with the Prehistoric Society of East Anglia), 3 p.m. Mr. R. A. Smith, "Our Neighbours of the Neolithic Period." 5.15 p.m. 1. Mr. H. J. E. Peake, "The Age of some Megalithic Structures in the Mediterranean Area." 2. Mr. A. L. Lewis, "Exhibition of Flint Implements, etc., found on the surface in Beddington, Carshalton and Wallington, Surrey."

Electrical Engineers, Institution of (Scottish Section), Princes-street Station Hotel, Edinburgh, 7 p.m. Mr. C. M. Jacobs, "Electrical Signalling and Control on Railways."

(Yorkshire Section.) Philosophical Hall, Leeds, 7 p.m. Dr. S. F. Barclay, "The Mechanical Design and Specification of the Turbo-Alternator Rotor."

(Manchester Section.) 17, Albert-square, Manchester, 7 p.m. Mr. E. B. Wedmore, "The Control of Large Amounts of Power."

Wednesday, March 13...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. M. Paul Lambotte, "Ypres and other Flemish Cities before and since the War."

Automobile Engineers, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m. Mr. F. L. Martineau, "Nomography, with a few references to its use in Engine Design."

Public Health, Royal Institute of, 37, Russell-square, W.C., 4 p.m. Professor W. H. Thompson, "Food in its relation to External or Useful Work."

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m.

Metals, Institute of, at the Chemical Society, Burlington House, W., 8 p.m. Annual General Meeting. Presidential Address by Professor Carpenter.

British Acetylene and Welding Association, Holborn Restaurant, W.C., 2.30 p.m. Captain D. Richardson, "Notes on defective Oxy-Acetylene Welds."

Japan Society, 20, Hanover-square, W., 3.30 p.m. Mr. W. Gadow, "Glimpses of Old Korea."

Thursday, March 14...Royal Society of Arts, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. W. Foster, "English Commerce with India, 1608–1658."

Aëronautical Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 8 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Metals, Institute of, at the Chemical Society, Burlington House, W., 4 p.m. 1. Mr. J. N. Greenwood, "The Relationship between Hardness and Constitution in the Copper rich Aluminium-Copper Alloys." 2. Messrs. H. Whitaker and H. Rix, "Aluminium Bronze Die Casting." 3. Dr. G. H. Gulliver, "On Grain Size." 4. Mr. O. W. Ellis, "Lead-Tin-Antimony Alloys."

8 p.m. 1. Professor H. C. H. Carpenter and Miss C. F. Elam, "An Investigation on Unsound Castings of Admiralty Bronze (88 : 10 : 2): Its Cause and the Remedy." 2. Kinematographic Exhibition, "Canadian Water Power."

Royal Institution, Albemarle-street, W., 3 p.m. Sir Alexander Mackenzie, "War Music: Past and Present." (Lecture II.)

Camera Club, 17, John-street, Adelphi, W.C., 8.15 p.m. Mr. F. J. Mortimer, "War Time Printing Processes."

Historical Society, 22, Russell-square, W.C., 5 p.m. Mr. E. Lipson, "The Evolution of Capitalism in the Woollen Industry."

Optical Society, Imperial College of Science and Technology, South Kensington, 8 p.m. 1. Naval Instructor T. Y. Baker, "Reflecting Prisms." 2. Mr. T. Smith, "The Detection of 'Ghosts' in Prisms."

Paint and Varnish Society, St. Bride Institute, Bride-lane, E.C., 6.30 p.m. Discussion on "The Paint and Varnish Trades under existing Restrictions."

Friday, March 15...Royal Institution, Albemarle-street, W., 5.30 p.m. Right Rev. W. Boyd-Carpenter, "The Romantic Movement."

University of London, Slade School of Fine Art, University College, W.C., 4.30 p.m. Dr. T. Borenius, "Sixteenth and Seventeenth Century Art." (Lecture IX.)

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 6 p.m.

Saturday, March 16...Royal Institution, Albemarle-street, W., 3 p.m. Professor Sir J. J. Thomson, "Problems in Atomic Structure." (Lecture V.)

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 8, 1918.

No. 3408. MARCH 15, 1918. Vol. LXVI.

JOURNAL
OF THE
ROYAL SOCIETY
OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:

Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,408. VOL. LXVI.

FRIDAY, MARCH 15, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

WEDNESDAY, MARCH 20th, at 4.30 p.m. (Ordinary Meeting.) PERCY SHUTTLEWOOD, Ministry of Food, "The Food Situation in Germany."

Further particulars of the Society's meetings were published in the last issue of the *Journal*.

COUNCIL.

At the last meeting of the Council, on Monday, the 11th inst., Lord Leverhulme was elected a member of the Council and Vice-President of the Society, in place of the late Sir John Wolfe-Barry, K.C.B., F.R.S.

"TRUEMAN WOOD" LECTURE ENDOWMENT FUND.

On the resignation of the Secretaryship by Sir Henry Trueman Wood in 1917, the Council resolved to institute an annual "Trueman Wood" Lecture to commemorate the services rendered to the Society by Sir Henry during the thirty-eight years for which he had held office. In order to place the lecture on a secure and permanent basis, by providing a substantial yearly fee for the lecture, it was subsequently decided to invite past and present members of the Council to raise an endowment fund. In response to a notice circulated among them, the sum of £643 has now been subscribed.

THE ALBERT MEDAL.

The Council will proceed to consider the award of the Albert Medal of the Royal Society of Arts for 1918 early in May next, and they therefore invite Fellows of the Society to forward to the Secretary on or before Saturday, March 23rd, the names of such men of high distinction as they may think worthy of this honour. The medal was struck to reward "distinguished merit in promoting Arts, Manufactures, and Commerce."

The list of those who have received it since its institution in 1864 was given in the last number of the *Journal*.

FOURTEENTH ORDINARY MEETING.

Wednesday afternoon, March 13th; HIS GRACE THE ARCHBISHOP OF CANTERBURY in the chair. A paper on "Ypres and other Flemish Cities before and since the War" was read by M. PAUL LAMBOTTE, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique.

The paper and discussion will be published in the *Journal* of April 12th.

INDIAN SECTION.

Thursday afternoon, March 14th; The RIGHT HON. J. AUSTEN CHAMBERLAIN, M.P., in the chair. A paper on "English Commerce with India, 1608–1658" was read by Mr. WILLIAM FOSTER, C.I.E.

The paper and discussion will be published in the *Journal* of April 19th.

COVERS FOR JOURNALS.

For the convenience of Fellows wishing to bind their volumes of the *Journal*, cloth covers will be supplied, post free, for 2*s.* each, on application to the Secretary.

LIST OF FELLOWS.

The new edition of the List of Fellows of the Society is now ready, and can be obtained by Fellows on application to the Secretary.

PROCEEDINGS OF THE SOCIETY.

ELEVENTH ORDINARY MEETING.

Wednesday, February 20th, 1918; John Slater, F.R.I.B.A., in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Brocklebank, Rev. Clement Edmund Royds, London.
Drummond, George Henry, London.
Hobson, Arthur E., Connecticut, U.S.A.
Jou-lin, President Tsao, Pekin, China.
Leverhulme, Lord, London.
Marshall, Herbert J., Gainsborough.
Metcalf, Henry E., London.
Mortimer, Engineer-Commander John Ernest, R.N. (retired), M.I.N.A., M.I.Mech.E., London.
Ogden, Henry Joseph, London.
Pantin, Carl Frederick Abel, Second Lieut. R.E., London.
Pantin, Herbert, London.
Quin, Lawrence Howard, London.
Rodd, Charles, Poole, Dorset.
Stephens, Mrs., London.
White, Charles, Aberystwyth.

The following candidates were balloted for and duly elected Fellows of the Society:—

Bamber, Herbert Kelway, M.V.O., Datchet.
Campbell, Donald Fraser, London.
Galpin, Stanley M. A., Aylesbury.
Gell, John, M.I.E.E., London.
Gridley, Charles Oscar, London.
Hinchley, Professor John William, A.R.S.M., Wh.Sc., F.I.C., London.
Murdoch, J. Alfred, London.
Parkes, S. Thomas Hickling, Birmingham.

The paper read was—

SUGGESTIONS TOWARDS AN APPRECIATION OF THE PICTURESQUE CONSIDERED IN RELATION TO SOCIAL CONDITIONS AND ENVIRONMENT.

By Maurice B. Adams, F.R.I.B.A.

We are told that "the ancient homes of the people survive as sepulchres of the dead." This comment is not only incomplete, but most misleading. My object is to awaken an interest and not to promote a wordy argument, much less to premise a shibboleth. The title chosen for this paper is said to be too long, and others complain that the wording is obscure. Perhaps the confusion about our title may have arisen from a misapprehension as to what the word "picturesque" really means. The term is generally misused, and it is, of course, not exactly an equivalent to "pictorial." Certainly in its application to buildings or sculpture it implies much more, and cannot be limited to pictorial compositions set out on one picture field as in a drawing or painting. Picturesqueness is a relative quality, and De Quincey somewhere asked, "What is picturesque in relation to the beautiful and the sublime?" Sir Joshua Reynolds furnished an answer when he described a series of crosses as being "placed prospectively in an uncommonly picturesque manner."

This prospectivity of arrangement, architecturally speaking, comprehends the effect of a structure on all its sides, and judges the work likewise as to its particular purpose, its position on the site, and whether it must commonly be seen from above or from below. Accidents and decay may add to the picturesque, it is true, but we are treating of buildings, not ruins. The relation of a building to its environment is of great moment. A bleak and rocky open spot on a wild position demands a different edifice from one more suitable for a cosy coombe well sheltered by trees. The value of solids and voids comes into play; one feature governs another, thus determining the grouping and breadth of treatment. The proportions and perspective lines delineated as in a picture might exhibit a frontispiece from one point of view, but light and shade in the brilliant sunshine of June become absolutely another question during the half tones of a winter's dull day.

Thus we begin to understand the importance of skyline and profiles in silhouette and in the round. A water-colour sketch may be *chic* and effective, and yet be essentially misleading. Architecture is the mistress art, and must be more than a mere pictorial idea. She provides housing for man and beast, giving shelter for paintings, scope for sculpture, and opportunities for the arts and crafts. Architecture is not a matter of more or less stuck-on ornament. Its success and power of influence depend upon stability, form, and fitness because architecture absolutely is fundamental.

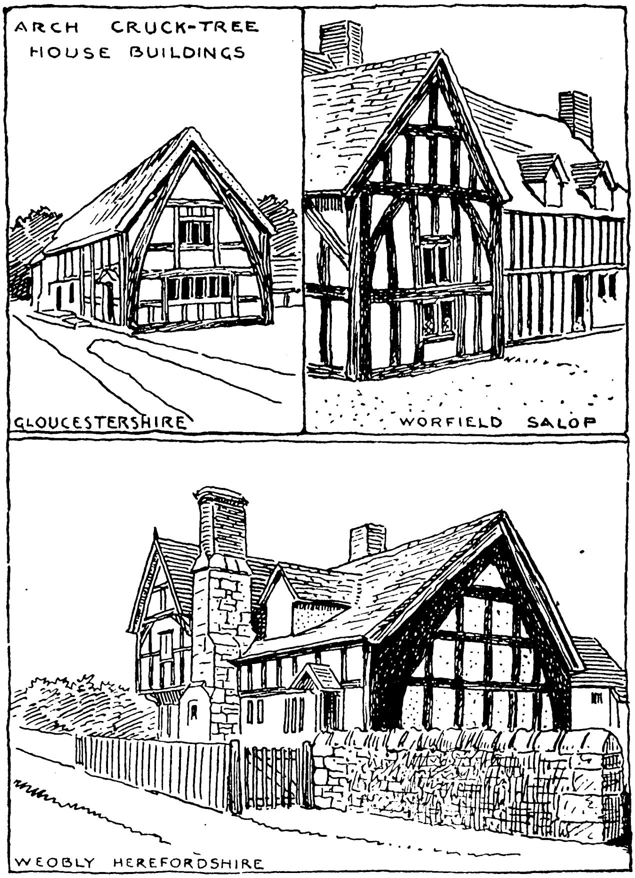
Paradoxical, however, as it may seem, one primary distinction must be admitted, and please recognise therefore the absence of any sort of presumption on the part of our old picturesque building work to rank as

architecture at all. It makes no such claim, and considered evolution in house-building in a precise periodical sense is unknown. Vernacular directness of construction and sublime simplicity made these indigenous structures what they were. All idea of preconceived quaintness was foreign to their genesis. They are not warrens of incongruous oddments or little kinks of incoherent buggaboo art and snobbishness, emulating their betters.

Such work is so primitive and so natural that it cannot nowadays be successfully repeated, and when attempts are made they result in incongruities. There was no make-believe about the builders who put them up, and therefore we glory in these delightful old cottages and rural buildings. They had no stylish notions, and what our ancestors built was spontaneous and new—therefore reasonable and pleasant. The manner adopted arose from daily needs and local materials ready to hand. The old-time housings are for all time understandable, and were inspired by individuality of character, by practical and traditional methods, thus giving the work of different countries local distinction. The craft employed was coherent, though at best, perhaps, little more than a sort of naively inspired rule of thumb without oblations of style. The beauties of British folklore, crude as old ballads or rhythms may seem, are undeniably human and devoid of the mannerisms of "polite literature." Chaucer, like Danté, employed the vulgar tongue. The spirit of the language is the most important key to the spirit of the people. The old craftsman inspired his job with the personality of individual charm, also intuitive harmony, rough in expression, but unsophisticated and native. He worked leisurely, putting his mind into his work because he enjoyed the task untrammelled by trade unions, though likely enough he belonged to a neighbouring guild of artificers. After the more primitive erections of timber gave place to stone buildings, the carpenter long occupied a very inferior position, most of the work being in the hands of masons. As a result, woodwork became illogical, inasmuch as timber construction imitated the methods peculiar to stone. For instance, when a wooden chest had to be made, a balk of oak was hollowed out like a stone coffin, or, if a wooden altar tomb was required, the carpenter employed big slabs of stuff, dowelling them together to represent stone with arcades copied from masonry and coloured to match. Sir John Pitchford's tomb, at Pitchford in Shropshire, I show so that you will see that traditional work was not always consistent in this respect. Later on, when woodwork obtained its mastery among the crafts towards the close of the fifteenth century, the carpenter turned the tables on the mason, who, in his turn, emulated the triumphs of timber by endeavouring to copy wooden detail in stone. A few facts of this fundamental kind have to be kept in mind when considering the basis of the picturesque.

Building by-laws were very few even in London during the Middle Ages. The main problem was the manner of roofing, and this influenced the shape of all buildings from remote times in all countries. The country homes of England in earlier times had no fireplaces or chimneys, and very few windows. Smoke flues eventually revolutionised, and, of course, enormously increased the picturesque outline of all dwellings, to say nothing of their comfort. The virility of the art of building, and especially the planning of houses, depended on details incidental to contemporary requirements as the counterpart of everyday customs carried out in an artless, straightforward way. The fashion, such as it was, resulted naturally in this simple manner. The worker in that sense was master of his craft, and emulation induced one good artificer to copy the better work of another, but the outcome, as a whole, was not imitative as a revived use of previous periods.

The Gothic revival of mid-Victorian days failed for that reason, though the result was an enormous success. The movement had a vital power of its own as the outcome of the Tractarian revival in Oxford. Most excellent churches have been built on Gothic revival lines, but the school of Mediævalists, like the cult of the pre-Raphaelites of yesterday, has had its day. The enterprise, however, was unique, picturesque, and inspiring. Impressionists and Cubists are to the fore meanwhile, and at present there is no common school of considered thought in architectural design. There is no lack of literary dexterity, and enterprising professors vie with each other in the use of paradoxical phrases; but all the coteries, with their disputations and conferences, cannot get over the hiatus between the present and the past owing to the elementary fact that they cannot bring back our lost traditions. New art is an absurdity, inasmuch as there are only two kinds of art—the good and the bad. The best is artless, hence the mere outwardly equipped artist or schoolman has no abiding pregnancy in spite of his technique,



of tradition. Scholarly academic productions belong entirely to another category, and when most correct and mechanically true to pattern they correspondingly fail. This lack of success arises from the absence of inventive imagination, the Divine afflatus—

> "What boots it thy virtue,
> What profit thy parts,
> While one thing thou lackest—
> The art of all arts?"

The intuitive artist cannot be fettered in that way: therefore, if he be rightly directed, precedent serves his purpose primarily as a formative medium of expression, and he takes precious good care to employ structural materials so as to preserve their relative scale of colour and natural texture. Finish and manner of jointings in all trades of building work are of extreme importance, and an artist worthy of the name has no fear whatever of making his work look new. He builds for to-day as well as for posterity, so time alone can test his work.

Local materials ought always to be locally used by old methods of handling without admixtures of foreign importations, unless a district happens to have no good materials of its own. On the banks of the Nile mud-clay stands better than ferro-concrete faced with stone ashlar. The blue slates of Wales look well enough midst the national mountain uplands, but no more ugly and hard-looking material can be used in a brick country like Sussex. The well-timbered countryside produced wood-framed houses, and where stone abounded masonry of course prevailed. Thus architecture naturally was native, forming part and parcel of the landscape.

which at first sight seems so captivating. Intuition is only hampered and stultified by erudite artifice. Creative art cannot be evolved by copying extinct styles, though, on the other hand, progress must ever depend upon a digest of what has gone before, and, provided such knowledge is stimulated by a recognition of the whys and the wherefores of historic design, development is assured. That is my reason for insisting so much upon the atmosphere surrounding the subject under our consideration, as to what actually constitutes the real character of the picturesque, not that I can hope to put forward anything new in detail. Egotists have tried to become emancipated and so, in order to become original, sought to ignore the alphabet of the arts, so the upshot of their amateurish essays failed. That sort of thing speedily tires, does not mature, cannot weather well, and being emasculated is incapable of repetition.

In judging architecture, qualifications have to be observed as to scale, cost and purpose, as well as the influence of differing materials. Workmen now have no idea whatever as to the meaning

Our inquiry begins with the Middle Ages. The troglodytes and pre-Conquest tenements or shelters of the Romany people need not detain us, though an occasion will occur for reference to the huts of old charcoal-burners of the past. The earliest wooden structures had to do with bent-tree roof construction, which obviated solid sidewalls. The "crucks," or balks of timber—hence the word rooftree—set "the wrong way up" on pieces of stone or slabs laid on the earth. In this manner the

ridges and weight of the roofings were carried independently of vertical walling. Oak, elm, ash and beech timbers were employed, but chestnut wood only rarely. Basketwork and wattle daubed with mortar or mud served for the panels of framed structures, and filled in the interspaces in lieu of walls. In Stuart days brick fillings called "nogging" came into vogue; it was very heavy and in time sagged badly. The earliest building with timber walls is the Saxon church at Greenstead near Ongar in Essex. The construction of wooden roofs reached its climax during the sixteenth century when the wright did most of the work, still using the adze for shaping and squaring the timbers, which were cut into balks by the pit saw. The plane and moulding stocks were then unknown. The adze and the chisel gave a personal finish and charm of texture or touch, as may be seen by the church screens and bench-roods in Devonshire and Suffolk. The work was not done to one dead level by the smoothing plane and sandpaper.

Oak shingles on roofs and weather boarding for walls gradually became more common, but thatch served for roofing in half the counties of England. Stone slabs were usual in the north parts of Cheshire and in Dorset. The risk of fire before engines were employed was met by erecting timber houses so unsubstantially that their frontages could be easily pulled down bodily into the road, and in the thirteenth century London aldermen and urban officials were provided with long iron crooks for this purpose. In the Moot Hall, Thaxted, Essex, a pair of such hooks can still be seen, and in other places also examples have been preserved. They were used as late as the Great Fire of London in 1666.

In order to realise in some degree the atmosphere, so to speak, of the fourteenth century, allow me to give an inventory of a specimen house of the better class of craftsman within the walls of the metropolis in 1337. My particulars are extracted from a legal indenture concerning Hugh de Bevere, who was murdered that year. The house which he occupied comprised two apartments, one above the other. The lower room had a door opening on to the street, and served as a kitchen or keeping room. It had a chimney and a fireplace. Light was obtained by one window, the upper part only being glazed and a shutter closed up the remainder. At the back of the premises stood the buttery containing six wine casks. In the living room a trestle table and two chairs were the only furniture, but there were several serviceable utensils—a grate, some hanging pots, andirons, basins, washing vessels, iron horse, cooking pot, frying pan, a funnel, and a pair of ankers or tubs. Access to the upper room or solar was obtained by a ladder through a space left open in the floor. The house was all of wood, but in accordance with the city regulations the party walls were of stone. This sleeping room contained a bed with mattress on it and three feather beds, also two pillows. A big chest or coffer stood against the wall, stored with six blankets and one serge or coverlet with shields of sendal, a kind of thin silk, eight linen sheets, and four table-cloths. Alice le Bevere, the newly-made wife and so soon a widow, looked with justified pride on the contents of her press. A candlestick of "lattone," two plates, an aumbry, and, for luxury, they had curtains to hang before the door to keep out the cold, cushions, and even a green carpet. No glass mirrors, pictures, forks, no pins, and no writing paper; also no soap, for that was little used. The development of ruffs and wide collars many years later was due to the general introduction of soap. The humbler dwellings had beds formed of a heap of straw upon which a whitel, or blanket, was spread. The floors were of earth and strewn with rushes or reeds. Parliament and the City Fathers passed stringent orders from time to time to prevent the defiling of the Thames with rushes and refuse turned out of the houses of London into the river, which was generally so bad that plagues were periodically caused.

The fragile wattle framings of the walls made of "raddle and dab" enabled thieves to gain an easy entry; hence the term "house breaking" survives. In the West of England "cob" is the dialect name of mud walling which dates from Babylonia, thousands of years ago. The Ancients ornamented their mud buildings with stone pins pressed into the clay in quite beautiful patterns, and you will notice how admirably the rounded formations suited the material, as shown by the walls of Warka, in Chaldea.

Cob cottages were both cheap and warm, as well as durable. Road-sweepings were employed in layers intermixed with the clay, or straw at times was worked in to give it a bond similarly. In London in 1189 clay was thus used, but the material cracks sufficiently to harbour bugs and pests.

During Elizabeth's reign, stone rubble foundations were used for cob cottages and thatch covered the roofs as at the present day. I show a good pair, including Cockington Forge, near

Torquay. Chalk mixed with clay will be found in cottages about Devonshire, and chalk built up in brick courses occurs in Wiltshire about the district of the great White Horse. In half-timber framed houses the wood muntins and plates projected in front of the stucco panels at first, but when, for cheapness sake, the timber was wider spaced the plastering was finished flush. This facilitated rot, and when the work began to perish the framings were rough casted all over or hung with tiles and weather boarding. Stucco is a splendid material for lasting, and is easily ornamented with fine effect as at Clare and Wyvenhoe, in Suffolk, to mention only two of many fine examples. The rough timberings left exposed inside framed houses were covered by tapestry in the dwellings of the rich as already mentioned, but in manor houses the plastered panels were sometimes papered over, and in evidence of this I give a slide from Borden Hall, Kent, with two patterns of paper fixed up with flat-headed nails and dating from 1600 to 1650. The walls in this room were battened over, and so these papers were hidden up for, say, two hundred years. These old papers were printed from small blocks as used for cotton-printing. The ornament, rather Indian in style, was in black on a vermilion ground picked out in bright turquoise blue. At Ightham Mote, in the same district, there are some Charles II. wallpapers, but it was not till the eighteenth century that paper-hangings came into general use. Originally they were made in small squares, very difficult to match when fixing the paper with nails.

William Morris was the pioneer who first improved wallpapers, and he copied his charming schemes from "Gerarde's Herbal," wherein the flowers are drawn out like pressed specimens of plant forms. His sole exception to these conventional shapes was a fruity fancy for pomegranates spread bountifully over everything in a gorgeous glamour of mediævalism.

Morris was trained as an architect under G. E. Street, and this reference to him recalls the furnishing firm which he financed and founded in association with the pre-Raphaelite brotherhood to whom the credit belongs of endeavouring to endow Western Europe in the sixties with æstheticism. Every praise is due to these enthusiasts for heightening the prestige of applied art and influencing taste among thinking people. The prevailing impression of the cult was associated with peacock's feathers, sunflowers, a rage for blue crockery, and suffused with the smell of the virgin lily. In actual life William Morris and his friends were by no means lily-like or actually so ascetic as is supposed. They were reactionary and anti-scientific, and, like dukes and bishops, were machine haters, science haters, rule-of-thumbites to the bone. They promulgated Fabian Socialism as a protest against commercialism, also the condition of taste brought about by the 1851 Exhibition and Manchester prosperity. None the less, these emancipators recognised that their professional programme had money in it.

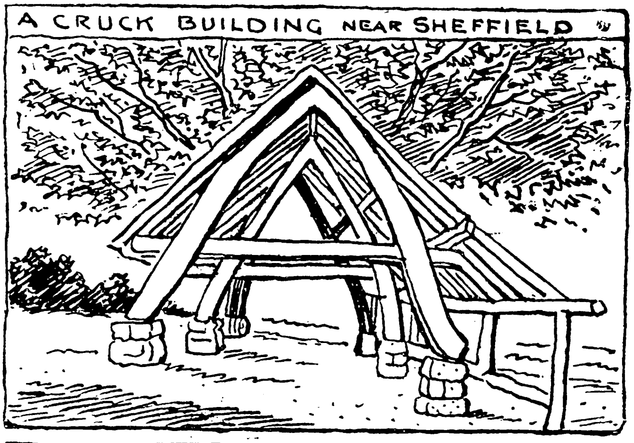
Stone houses do not appear to have proved much more durable than those built of other materials, though we see more of them as they were in the aggregate more numerous. After the Reformation, when agriculture lost the support of the church and ruined monasteries, a great many dwellings of all sorts fell into a bad way and perished. The development of roads led to stone wallings being used as quarries for making highways. Built of unjointed rubble mostly, the work was easily pulled down. If you examine this old masonry you will observe that the old builders in a natural way put the bigger blocks at the base, and gradually diminished the sizes till the top courses were reached. The quoins and jamb stones to the openings being random-shaped tailed into the rubble. All this simple contrivance gave much picturesqueness, and in the thirteenth century a sense of scale obtained by employing small blocks of stone with countless wide joints then the rule. When, however, Gothic work ran to seed, two centuries later, big stones and fine joints diminished interest, and the effect of proportion was lost. Stone slabs and slates for covering roofs were also laid in diminishing courses from eaves to ridge.

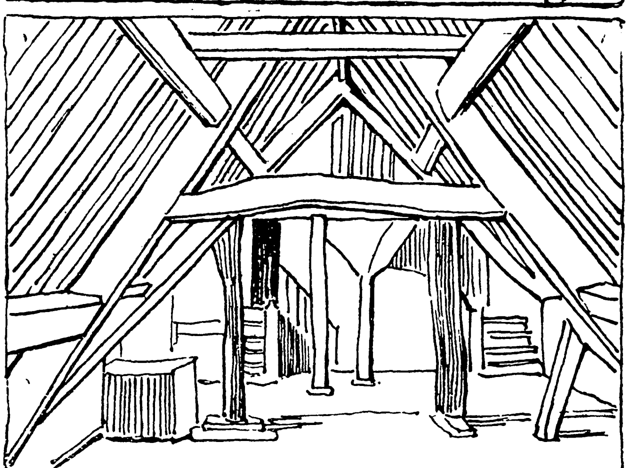
Mortar of mud remained in common use till the beginning of the nineteenth century, when lime mortar for better-class construction prevailed. Wide mortar joints garnetted with flint chips, after the manner already spoken of in Chaldea, can be seen in various old hamlets, as in Surrey villages. The origin of brickwork in England is obscure. Two very early instances of distinctive brickwork are Caister Castle and Little Wenham Hall in Suffolk, but probably the bricks came from abroad. Sussex vernacular brick quoins to flint wallings make a countrified and suitable job. Snapped flint and flint rubble made most durable and beautiful walls, specially in East Anglia, where it was rich. Colleges, churches, and houses had earth floors. These floors freely absorbed nitrous matter, and not infrequently bones were hammered in

to add geometric patterns, and also to harden the surface. This practice lasted till the end of Queen Anne's reign. For many years prior to that officials, called "saltpetre men," invaded buildings to dig up the earth floors in order to obtain nitre for making gunpowder from the floors of cowsheds, stables, and country houses. Bullocks' blood at this time was used mixed with the earth to harden the surface of mud flooring, take a polish, and prevent dust. Soot mixed with blood also served as a paint for colouring the inside timbering of dwellings. The first joist and wooden framed floors were used in Norman castles with cross-beams, from whence developed the familiar practice of oversailing the upper stories of domestic buildings. Thick planks and solid wood stair-treads were at first the rule, but as timber got scarcer thin boards and built-up stairs came in. Ordinary dwellings prior to the fifteenth century were seldom built more than two floors high. Staircases were rare; consequently the commonalty clambered up to bed by way of ladders or by means of pegs projecting from a central post, and these pegs gave a hold for feet and hands. The description of the London house previously quoted is a case in point. Staircases in the seventeenth-century yeoman's house and farmstead dwellings were often contrived in an awkward fashion, mostly cramped in by the side of recessed open fireplaces, and unequally built with odd-shaped winders and pinched in quarter landings set around the flue which also, quite likely, was an addition. The floors varied a good deal, and now and again very little headroom was allowed. Four-post bedsteads with heavy hangings were a necessity to keep out the wind, for these rooms were very draughty, though distinctly picturesque. Straight stairways sometimes were put under pents outside and considered sufficient, for our ancestors lived most times very much out of doors. A delightfully quaint outside stair is exhibited from Denham. In Jacobean days dog-legged staircases in short flights, with massive newels and quarter spaces or half landings furnished the favourite method in better-class houses. In historic houses stairs were very narrow and low, so big pieces of furniture were reckoned as belonging to the premises and formed part of the tenancy. No doubt it must have been very difficult to engineer coffins down most of these old, quaint staircases. This trouble is amusingly exemplified by the story told in "My Own Times" by Lady Dorothy Neville. A doctor advised an elderly lady, who much needed a change, to take rooms in an old farmhouse with which he was familiar and situated in an exceedingly healthy part of the country. His patient accordingly visited the place to make arrangements, and before leaving, having noticed the damaged staircase, said to the farmer's wife, "Before I come to stay with you the missing balusters must be made good for the stairs look so dangerous." The good woman replied: "Madam, that would be a needless expense to put us to, as the undertaker's men would only knock the balusters out again when bringing down the coffins."

The introduction of fireplaces was a revolution. For ages the smoke from smouldering embers of peat or wood was left to filter through the thatch of the roof or escape, if it could, under the eaves or get away through the gable hole which was provided as a vent fitted with a stone slab worked on a vertical pivot to shut up in bad weather. The lingering smoke thus oozed out gradually and deodorised the interiors. Sweet herbs were scattered over the floors of old churches and houses, but at best could have afforded only a temporary disguise to more pungent odours. Chimneys were gradually built to old houses, but even so palatial a mansion as Penshurst Place, Kent, still retains its brazier set in the centre of its magnificent hall floor The smoke has to get away through the louvres of the open-timbered roof big turret. Such picturesque discomforts do not seem to have troubled our forefathers, who survived many disagreeable inconveniences. Chimneys greatly modified the style of house-planning, and stately ideas, suggesting balance of parts, owe much to their introduction. Interiors gained by the importance accorded to the chimney-piece, and almost each generation added to their display and comfort. Chimneys in Tudor days grew to be highly ornamental, grouped together in a dignified way, diversified with weatherings and set-offs, often foliated or carved into diapered patterns. East Barsham Hall in Norfolk, Hornham Hall, Essex, and Huddington Court, Worcester, occur to the mind as specimens, as at Hampton Court. Parapets, as well as corbelled bay windows and chimney corner projections made also highly-pleasing features. Cottages had wide, oversailing eaves as the chief opportunity for effect with a deep shadow between the roofing and the walls. This is of essential value because it emphasises the horizontal lines which must prevail in elementary forms of domestic architecture. The overhanging of upper floors, which always looks

so picturesque, also kept the walling below very dry and gave a needed shelter. Small buildings, to be effective, ought to be handled as the old ones were in a big way, avoiding vertical lines because they cut up broad composition. The heavy eaves, on the other hand, give the effect of size and serve the practical purpose of throwing the roof water away from the walling. Guttering, even in town houses, was scarcely ever used. In the Middle Ages thatch had to be limewashed according to law as retarding fire and germination of "thatch fleas." The methods adopted to weight down and firmly fix the thatch added greatly to its delightful appearance





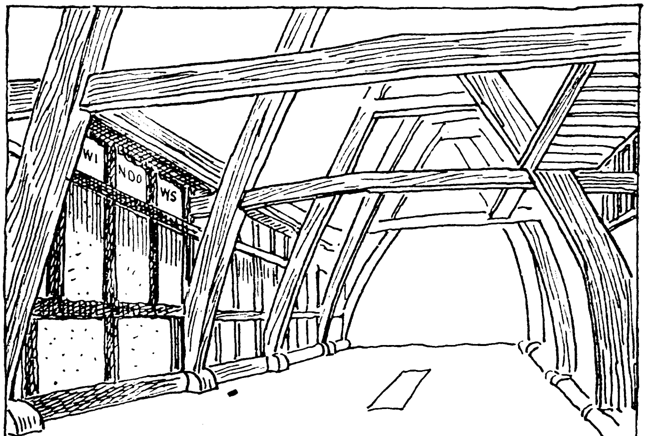
Doorways in many places were low and small, being made primarily with a view to defence more than convenience. Often enough in Stuart times the doors scaled no more than 4 ft. 6 in. high. The "heck" or "hatch" door, made in two heights, hung to open outwards independently of each other, was quite common, and the top half was of open lattice to admit light because windows were not often provided in the older cottages. The mullioned windows of the thirteenth-century dwellings were fitted with running shutters in superior cases. Lead cames followed only when glass became available. Oiled canvas served in the absence of glass, and the Chapter House windows of Westminster Abbey, as late as 1253, were treated in this manner.

Sash windows became the vogue in the time of the Commonwealth, but to save expense many were not made to open, and later on sham windows to ensure a uniform integrity of fenestration were adopted. This had the sanction of Sir Christopher Wren, as in his grand additions and Fountain Court at Hampton Court erected for William of Orange. The window tax shut up a vast number, and to this day the industrial classes have a decided objection to fresh air even in garden cities. There was no water-supply in old-time houses other than wells; and baths, as fixtures, belong to our own day. When Grosvenor Square was built few of the big mansions had proper bathrooms.

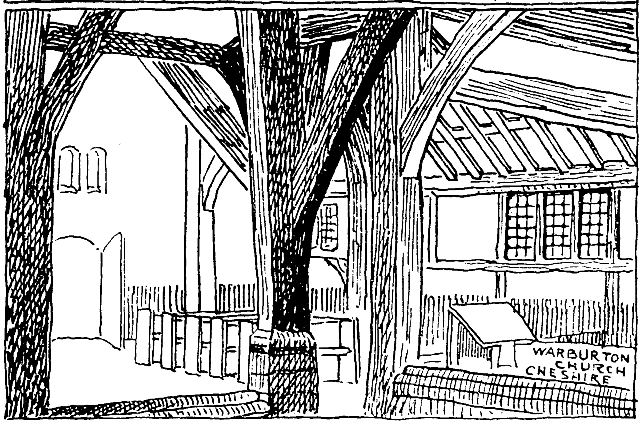
Reverting to the simplicity of the scheme of cruck timber framing, I wish to show how the method subsequently developed, and we have already seen a charcoal-burners' hut near Sheffield, for which I am indebted to Mr. C. F. Innocent, as also for several other details about the cruck method of building, and the history of this subject of timber work as described in his book on "The Development of English Building Construction."* I show also the top story of a fifteenth-century dwelling at Abingdon, a sketch of the attic of Kelmscott Manor, William Morris's Surrey house, a drawing of one of the aisles of Leominster church near Arundel, and the interior of Warbarton church, Cheshire, all in timber. The last is like the barn in the same county at Arley. Finer still is the Grange Barn at Alciston, Sussex, with its almost cathedral-like effect.

* Cambridge University Press, 1917. 10s. 6d.

The proportions of house roofs long continued to be of vast size in one span, thereby ensuring distinction of scale and ample room for storing, every house having to be self-reliant for supplies. In historic domestic buildings long low lines prevailed, and the height of pitch from floor to ceiling was seldom more than sufficient to stand upright in. Very few old dwellings had communicating passages, one apartment leading haphazard into another. People paid no attention to personal retirement, and the sexes were not particular about privacy. The floor boards and joists of the upper apartments in such places were left exposed, and the unplastered ceilings allowed the dust from above to drop through the flooring, while every movement was audible from below. The kitchen, or keeping place, invariably formed the chief room for the household use. Wash and brewhouses were ample and adjacent. Big brick ovens projected in a picturesque fashion externally alongside the added chimney corners.

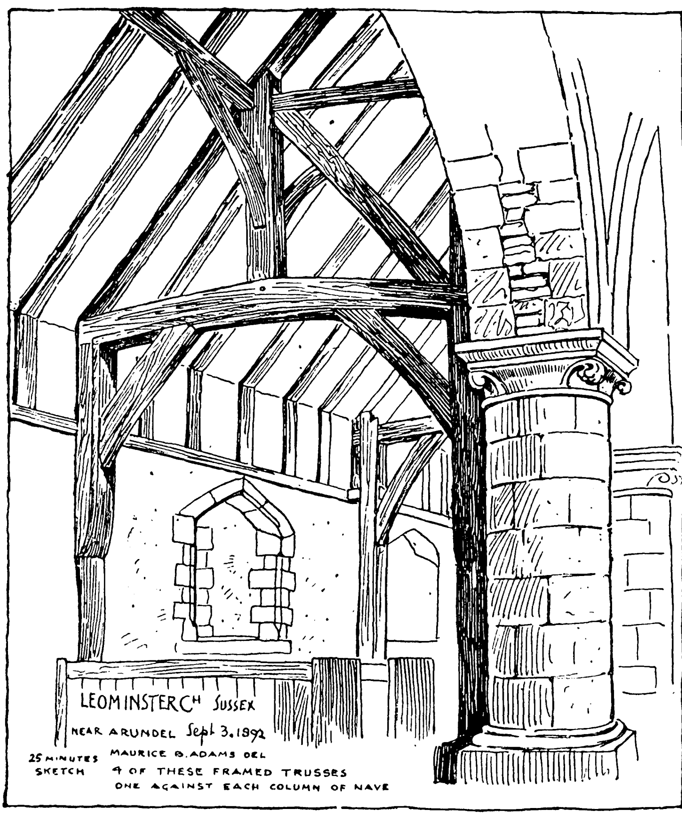


CRUCK ROOFING, ARLEY OLD BARN, CHESHIRE



Early in the last century the older folk resisted the provision of regular meal or dining-rooms as a new-fangled notion, and as for ablutions of the body, such a practice was thought necessary only for "dirty people." Sea bathing was, in fact, ignored till George, then Prince Regent, made Brighton fashionable by erecting the Royal Pavilion, and Mother Gunn supplied the bathing machines. Sanitary conveniences were not considered. The term did not occur in their vocabulary, so you will look in vain for the word in old dictionaries. Drainage remained dangerous and inefficient for many years after Victoria came to the throne. The basement of Eton College Chapel one hundred years ago formed a big sewage tank, with sluices opened once a week to allow backwater from a tributary of the Thames to act as a sort of inefficient flush, and this was the only outlet for the filth collected from the college buildings. The comely houses of Queen Anne, and the formal dignity of Georgian homes, ignored proper amenities in this matter. Prospect even was reckoned of little account before the coming of Dutch William, when only the best houses were placed with reference to the available view. Many things which we take as a matter of course were undreamt of in the fifteenth century, when the stately creations of the Renaissance flourished on the Continent in all their grandeur, when men of letters, giants of politics and geographical discovery, abounded, when Michael Angelo and Benvenuto Cellini excelled in fame. No retrospective glance at the picturesque broadly considered, would be adequate without a passing reference to those brilliant times, but probably never a period existed of more extreme depravity, the age of poison and the dagger. Men and women broke the Ten Commandments well, and counterbalanced affairs by doing beautiful work equally well. Beauty was rigidly relegated by the Puritans of the Commonwealth, though shocking things were done with an air of sanctity. Extravagances continued, as recorded by Pepys, in Stuart times and during the Dutch wars. These practices

flourished under William of Orange when Sir Christopher Wren built that king's noble wing to Hampton Court Palace. Passing on, we reach the four Georges, and in this excursion we fall in company with our great satirist and painter William Hogarth, and we meet the less known George Crabbe of Aldeburgh, whom Lord Byron described as "nature's sternest painter and first poet of his time." These worthies with masterly humour painted with graphic vividness many amusing though terribly sordid doings in high life, as well as below stairs. Hogarth's grim realisms, in his pictures of "Beer Street" and "Gin Lane," give an idea of public depravity which prevailed under Protestant rule after the failure of the notorious "Gin Act," when retailers did a roaring trade and advertised on signboards outside their shops inviting folks "to be drunk for a penny, dead drunk for twopence, or have a suck of Holland's through a straw for nothing." "The Reminiscences of Cambridge," by Henry Cunning, presents an intimate notion of morals and undeniably gross conduct which obtained in our universities of learning towards the end of the eighteenth century, when churchmen behaved very badly. Considering the deplorable standard of social life at this time throughout Europe, such a climax need perhaps cause little surprise. Pews and "three deckers" in churches may have been picturesque, and incumbencies were treated as privileged freeholds. The pews owned by the rich were furnished like parlours to doze in, and the poor were relegated to "free seats." Before "the Reformation," mural stone benches in church aisles were used by the sick and aged, hence the saying "the weakest go to the wall." No doubt in the fourteenth century many churches were furnished with elaborate stalls and benches, particularly in the west of England and East Anglia. A few admirable Jacobean examples, the forerunners of pew boxes of later days, may also be quoted, and very picturesque they are. Rolandson and Gilray, by their cartoons and coloured prints, leave no doubt about the flavour of affairs both in the Church and State. Wit was then ingenerate, sarcasm pungent, and humour bawdy. The story of "The Four Georges," by Thackeray, bears witness, and to carry on further we recall the characters depicted by Charles Dickens, whose account of Marshalsea, the Fleet and Newgate Prisons are not forgotten, in company with Fagin, the picturesque practitioner Pecksniff, and Bumbledom, when workhouses furnished a landmark as a dire blot on our landscapes. This brief review will suffice to exhibit how desirable it is, in considering our architectural studies, to redress prevailing ideas concerning the relative conditions distinguishing periods of British manners both before and after the Reformation.



Much of the beautiful work already described belonged to the so-termed "Dark Ages": therefore, to appreciate the influence which inspired it, we must look fairly in the face outstanding facts and bring into account some things which, taken apart on their merits, might at first sight seem to be outside the limits of this subject. All that concerns humanities,

however, does intimately matter as to their homes. To be practical, we cannot afford to ignore the best evidence obtainable: consequently with your forbearance it will be germane in this regard to give a few figures before concluding our brief summary of the normal affairs of our ancestors, and the circumstance during the ages when these picturesque houses and little hamlet churches were built. I am anxious to avoid carefully authorities influenced by ecclesiastical predilections, and I therefore have chosen William Cobbett, who certainly cannot, with any degree of truth, be suspected of any such partiality or limitations. When he wrote the following particulars, he was correctly reckoned an authority and considerable spokesman on the land question when Churchmanship was at a discount. These are his words: "The general idea is that before Protestant times England was comparatively insignificant, having few people in it, and those few wretchedly poor and miserable. Whereas all the parishes about the land are still in point of size what they were a thousand years ago, except where they have been united, and two or three or four even have been made into one. The County of Norfolk is the best cultivated of any one in England. In 1830 Norfolk had 731 parishes, and formerly the number was greater. Of these parishes twenty-two now have no churches at all: seventy-four contain less than 100 souls each, and 268 have no parsonages, whereas in old times every parish had a church and house for the parson. Is it a sign of augmented population, ease and plènty that out of 731 old parishes in Norfolk 268 have suffered the parsonages to fall into ruins and their sites to go waste?"

The last census prior to the present war brings our comparison up to date as nearly as can be stated. There were then 731 old parishes in Norfolk, ninety-seven of which made a return showing that each of them only possessed less than a population of 100 individuals. This year of 1918 the old parish of Upper Eldon in Hampshire has only three dwellings in it, one a farmhouse and two cottages, with a population of nine souls. The church belongs to the twelfth and thirteenth centuries with a rectorial area of 276 acres. Is it to be wondered at that agriculture has suffered?

The countryside was well populated with a prosperous and happy people when the old houses of which we have been talking were built, and the ancient sanctuaries of England came to be set up, but after making every allowance the fact remains that in the aggregate, since the Crown robbed the Church of its ancient holdings and appropriated Ecclesiastical supervision of the countryside, agriculture has suffered badly. Autocratic kings and ambitious politicians felt the inconvenience of clerical dominance. Though the monks were landlords, they did not become rack-renting landlords, and could not become absentee landlords. Truth to tell, the English clergy during the Middle Ages were honourably distinguished for their morality as compared with churchmen on the Continent. Hunting saved the situation in this country, where the "Hunting Abbot" was succeeded by the "Hunting Parson." The love of sport as a factor was a godsend, and had a restraining influence upon both parsons and people before the drab days of the smug Puritans, who sought to rob life of innocent picturesqueness, the killjoys in this workaday world where there are sufficient real sins without inventing imaginary ones. Before the days of the Reformation the Church was a world to live in, and not a building to go to, it was the centre of every parish, and churches were not only used for worship but served for a variety of semi-secular purposes. Religion entered into the common life of the people. Church plays were picturesque, and Morris dancers let themselves "go" for the amusement of the laity in a free and easy way. Of course there were comic parts, and in this pious drama a spade was called a spade. Some of the characters were far from refined in the tea-room sense, but the intentions of the players were healthy. When visualising the picturesque and considering the environment of such a community, always at war with necessity and emerging from the twilight of primitive conditions, it is necessary to take into account a few pertinent facts, and among such occurs the intimate familiarity first-hand with death, an unquestioned belief in the realities of the future state, the immortality of the soul, the personality of the devil, as well as of the Deity, and the imminence of the Day of Judgment. They sculptured their demons as they handled their pets, and the last ordeal, the weighing of souls, constantly furnished a popular subject for mural decoration. Satan possessed at least an individual charm in a sense that in these plays performed in church our forefathers were enabled to turn the flank of terror by forcing a merry and even jovial acquaintance with the unseen world. The uncanny wakes, with their incantations round

the bedizzened corpse, derived from pagan usages at the outset, were barbaric enough, but such orgies, nevertheless, had become in a crude way expressive of something more vivid by being based upon a reliance of hope which anyhow certainly is absent in the cold unpicturesque dignity of despair of our modern funerals.

Whatever the picturesque extravagances of the Mediæval church plays, they were incomparable with the bald directness and dirty drolleries which distinguished the seventeenth-century drama as best represented by sparkling Congreve and his emulator, William Wycherley. Their patron in chief was the beautiful Barbara, Countess of Castlemaine, who ended her days in obscurity.

The knockabouts and mummeries of the Middle Ages found a counterpart in the joy of the grotesques of the old masons and wood-carvings as in the misereries of chancel stalls, which excel in fun without suggestions of nastiness or loss of humour. The picturesque open-air processions which marked Rogation days, and the quaint services held for the blessing of seed-time and harvest as the seasons came round were interspersed by the festivals of "red-letter days." Think of the vast wealth of beautiful workmanship and artistic productions done everywhere at that period and compare them with the lifeless efforts of the "all buts" of our own time. "The yokel," as you call him, found what pleasures he had at home; he rarely travelled, and held the right of living on the soil inherited from the serfs. Open country was unknown, and England was so densely wooded that it was said a squirrel could traverse the kingdom without touching the ground. Witches and outlaws haunted the forests to the injury of loyal liegemen, but, notwithstanding, Shakespeare assures us the magic of the British woodland was "more free from peril than the envious court." Shakespeare, ever inspired with serene stagecraft, transferred his loved forest scenes from play to play. "Back to the land," he urges again and again because he knew it well, and his cure for human sins was a simple return to nature.

The pillage of our churches and religious houses by the government was resisted by our forefathers. This fact is abundantly clear, and the following quotation from the city archives of Exeter is a case in point from a contemporary record by John Hoker, chamberlain of the city from 1555 to 1601. He gives a picturesque account of the despoliation of the Priory Church of St. Nicholas in Exeter, when the "Comyssioners" appointed by the Parliament of 1535 came to this "Citie yn the somer tyme to exequute theire Commissyon and begynnynge first with the priorie of St. Nycholas after that they viewed the same they went thense to dynner and commanded one yn the time of theire absence to pull downe the Rood lofte yn the Churche. In the meane while and before they dyd returne certeyn women and Wyffes yn the Citie came yn at last to the said Churche, some with spykes, some with shovells, and some with suche tooles as they could geyte, and the churche door being fast they broke it open. And fynding there the man pullynge down the Roode lofte, they all sought all the meenes they could to take hym and hurled stones unto hym. In so mich that for his satifitie he was dryven to take the Toure for his refuge and yet they pursued hym so egerlye that he was enforced to leape out at a wyndo and so to save hymselff and very hardely he escaped the breakinge of his necke but yet brake one of his rybbes."

Norfolk has some of the largest and most beautiful churches in England, and the native artificers would be difficult to match nowadays with all our educational schemes and architects or schools. The people who did such work were not priest-ridden, neither was the country sparsely inhabited. The vast mortality during the Black Death and subsequent plagues proves the fallacy of such assertions.

The essentials of the picturesque are beyond the scope of superficial affectation, and it is due to that fact that so very few modern buildings are marked by that restful quality, because our contemporary work is too self-conscious and pretentious, lacking simplicity.

A dwelling is not an abstraction only to be reckoned as an adroit performance, a mere pile of timber and tiles, or bricks and mortar, peopled by a given number of souls. A house should possess a soul of its own, distinct and characteristic, a personal conglomeration of life with its own peculiar essences, flavour, and feeling as well as romance. The French emphasise this essential of a habitation by always speaking of the family residence as "the house."

Our modern disorderly England has changed materially during the last fifty years, and, strictly speaking, it is not an old country, but a new one. Sanitary science and surgery, the haphazard developments of industrial enterprise, the transport system, overcrowding of

industrial centres, repressive measures against land-ownership among many other political circumstances out of place to mention here, have combined to inaugurate a new age of experiment rather than consistent progress. England of the thirties was an old country, bearing a far closer resemblance to England of Tudor Elizabeth than that of George V. When Mr. Direck arrived in Essex from America he said "he thought he had come to the England of Washington Irving, but found it not even the England of Mrs. Humphrey Ward." Rural life, in the meantime, has been avoided for its dulness and monotony, but what we want in this country is more air, a keener understanding of picturesqueness and joy of life which is a question of balance, a fuller and freer social life. Better country housing is the problem of the hour. We have greatly overdone herd life, so that at the outbreak of the war three-fourths of the population was compacted in urban centres, leaving less than a fourth for rural occupation. The defacing disease of vulgarity is the natural product of herding in towns, and is by no means a matter of class. We have already realised the urgent need of the home production of food. The privations consequent upon the war have, therefore, accomplished much towards making the land question in the United Kingdom a practical and remunerative concern. We must sweeten our workshops, extend small-ownership, and promote the amenities for well-being; cleanse our dirty disorderly railway stations, consume our smoke, and improve the homes of those who are to be employed on farming and the production of foodstuffs, and this problem of tackling rural housing must be based on artistic and economic lines. Standardised cottages schemed on a schedule would inevitably prove a gigantic and enormously expensive catastrophe. All "arty" fuss and preconceived official ideas must be abandoned in favour of sound, well-shaped, straightforward, healthy tenements designed with strict regard to local materials and differing districts. Environment must not be ignored by the adoption of stereotyped plans. Every cottage ought to be made worthy of the name of home and be in harmony with the garden and the hedgerow. We cannot afford to spoil further the beautiful landscapes of England, and the rural charms of the countryside must be conserved by these elementary essentials. They constitute actually fundamental assets worth fighting for, but when the battle is over we shall need all our energies to prevent ill-considered schemes from being undertaken to the detriment of all classes and real prosperity. The achievements of the past and the experience of the ages which made England great must be brought to bear upon the task which lies before us in the near future. "Idealism has ever been the great driving force of all history." Let us not perpetuate makeshifts, for they are futile.

The paper was illustrated by a number of interesting lantern-slides.

DISCUSSION.

The Chairman (Mr. John Slater, F.R.I.B.A.), in opening the discussion, said it was well to note that beauty and picturesqueness were by no means the same thing. For instance, in a Greek temple there were the most perfect accuracy of line and the most delightful proportions combining to produce a beautiful building, which, however, could hardly be called picturesque; whilst picturesqueness was obtained to the full extent in some of the Flemish town-halls, with their irregular plans, steeply sloping roofs and bulging gables. As the author had said, buildings to be picturesque must be real and not sham: he did not know anything more depressing than the sham classic structures which had been erected as ruins round Virginia Water. The author had said that the Gothic revival failed, and perhaps it did in one sense, when it endeavoured to carry the principles of Gothic architecture into practical use in buildings which were not suitable for them; but it had left some magnificent monuments, and, personally, he never ceased admiring the beautiful proportions and the wealth of detail of the Victoria Tower of the Houses of Parliament. He agreed with the author that in all localities the local materials ought to be used as far as possible; if that was done an architecture was obtained which differentiated one part of the country from another. An example of that was to be found in the Horsham flags, which gave a delightful effect to the roofs of Sussex buildings, with the play of colour caused by the lichens and the stonecrop growing on them. It must not be forgotten that plan was an essential feature both of beauty and of picturesqueness, and he could never without wrath find himself bound down by the terms of the London Building Act, which enforced an absolute line of frontage for all buildings facing London streets. He did not agree with the author that one must look to the Dark Ages for the greatest picturesqueness; many Elizabethan and Jacobean buildings were both beautiful and picturesque, and some Georgian buildings possessed the most delightful balconies that could be found anywhere.

Mr. H. H. Statham, F.R.I.B.A., in proposing a vote of thanks to the author for his admirable paper, said he agreed with practically every word of it. With regard to the definition of picturesqueness, he thought it depended a great deal upon

what was called "character," which was a quality very difficult to define. As the Chairman had said, a Greek temple was not picturesque, and it certainly had not character. He thought character was shown by what was done in order to meet some particular demand or taste of the person erecting the building. He agreed that the Gothic revival eventually failed; but, speaking as one who had been an architectural pupil at the time of the revival, he could say that it had one great advantage—it gave students a passion for architecture. The buildings that were erected shortly before the revival could not interest them very much, but when they began to study mediæval architecture they felt they had found a subject which it was worth while pursuing with passion and devotion, although the revival had not succeeded ultimately. The slide the author had shown of a charcoal-burner's hut reminded him of Browning's "Sordello," where he described the supposed beginnings of architecture, and spoke of the Stone man as "dreaming, and shaping his dream into a door-post." He was very much in agreement with what the author had said about the sham picturesque architecture of modern days. He had noticed that particularly in going over the recent garden cities. There one saw houses with very lofty roofs, which were not necessary now, and were only built in former times because the architects then had not sufficient knowledge of timber construction to make the roofs flatter. One also saw houses built with very small windows because old cottages had very small windows, in spite of the fact that there was no reason now to make the windows small, and that they were very unhygienic. Such cottages ought to be swept away, and garden cities should be formed of the best small houses that could be built at the present time, with the materials that it was the natural custom to use now. He had even thought—though people in search of the picturesque might be horrified at the idea—that houses ought to be built now with flat concrete-steel roofs. That might eventually be thought the best plan, and if it were adopted a method of treating that kind of building would very likely be found that would give it a picturesqueness and character of its own. At all events, in garden cities buildings should be avoided which aimed at being imitations of old houses which were unsuitable to our modern habits of life, and which were only imitated now because people thought them picturesque. They were not designed to be picturesque by the men who built them; they were merely the best that could be done at the time, and to copy them now was only to provide an elaborate sham.

Mr. W. Woodward, F.R.I.B.A., in seconding the vote of thanks, said the paper was a deeply interesting one, and afforded much food for thought. The last few sentences were of special importance at the present time. It was well known that the Government proposed to build something like half a million houses for the working-classes, and it was a matter of moment to everyone that at all events those that were built in the country should be built in a picturesque manner, without any standardisation, and with due regard to the materials of the particular localities in which they were erected. He agreed with the author that we should not be afraid of our architecture looking new, because there was no doubt whatever that picturesqueness was to a very considerable extent due to the effect of time. If he were to erect a lych-gate to-day precisely similar in design and production to a lych-gate of the fourteenth century, one would look picturesque, because of the growth upon it, the result of time, and the other would perhaps be passed by unnoticed.

The resolution of thanks was carried unanimously, and the meeting terminated.

CORRESPONDENCE.

INDUSTRIAL BANK.

An Industrial Bank supported by the Government, in this country, to my mind is now essential.

The amalgamation of large joint-stock banks does not help the small trader.

If it were possible, without issuing more paper money (which would destroy currency), to have or institute a Clearing House of the World's National Debts, this would bring money back into trades.

D. R. Broadbent.

GENERAL NOTE.

Dyes from Wattle.—Experiments conducted by Mr. James Weddell, of Natal, for the purpose of ascertaining the value of wattle extract for dyeing purposes, says *South Africa*, have so far proved successful that he claims to have obtained some thirty shades, ranging through browns, drabs, greys, and fawns. Tests made with woollens and cottons were satisfactory, the effect of washing being rather to darken the shades than otherwise. The secrecy which formerly surrounded the German dyes has been denounced by manufacturers as a myth, and it has been found that equally fast dyes can be obtained from several woods with permanent effects. Some of the khaki shades issued to the South African soldiers at the beginning of the war were most disappointing, for they would not stand a wash, being apparently produced in a hurry. Should the wattle shades prove to be lasting another industry will be added to the list already growing in South Africa.

Owing to the further restrictions on the supply of paper, it has been found impossible to include the usual list of "Meetings for the Ensuing Week."

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,409. VOL. LXVI.

FRIDAY, MARCH 22, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

LECTURES ON "THE FREEDOM OF THE SEA."

The Council have made arrangements for a special course of three lectures on "The Freedom of the Sea," to be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m. The first lecture will be given by Mr. GERARD FIENNES, the second by SIR FRANCIS TAYLOR PIGGOTT, LL.M., and the third by Mr. JOHN LEYLAND.

CANTOR LECTURES ON "MILITARY EXPLOSIVES OF TO-DAY."

The Cantor Lectures by Mr. J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, on "Military Explosives of To-day," will be given on Monday afternoons, April 8th, 15th, and 22nd, at 4.30 p.m., instead of 8 p.m., as previously announced.

INDIAN SECTION COMMITTEE.

A meeting of the Indian Section Committee was held on Friday, the 15th inst. Present:—

Sir Charles Stuart Bayley, G.C.I.E., K.C.S.I. (Acting Chairman of the Committee), in the chair; Sir Arundel T. Arundel, K.C.S.I., Thomas Jewell Bennett, C.I.E., Sir M. M. Bhownaggree, K.C.I.E., Sir Valentine Chirol, Colonel Sir Thomas Hungerford Holdich, R.E., K.C.M.G., K.C.I.E., C.B., D.Sc., Sir Henry Evan M. James, K.C.I.E., C.S.I., Sir Frederic S. P. Lely, K.C.I.E., C.S.I., Colonel Arthur H. Glendowe Newcomen, C.I.E., V.D., J. A. Voelcker, M.A., Ph.D., F.I.C., Colonel Charles Edward Yate, C.S.I., C.M.G., M.P., with S. Digby, C.I.E. (Secretary of the Section).

FIFTEENTH ORDINARY MEETING.

Wednesday afternoon, March 20th; SIR HENRY TRUEMAN WOOD, Member of the Council of the Society, in the chair. A paper on "The Food Situation in Germany" was read by Mr. PERCY SHUTTLEWOOD.

The paper and discussion will be published in the *Journal* of April 26th.

PROCEEDINGS OF THE SOCIETY.

TWELFTH ORDINARY MEETING.

Wednesday, February 27th, 1918; The RIGHT HON. LORD FARINGDON in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Alley, Stephen Evans, J.P., M.I.Mech.E., Shrewsbury.
Briggs, Francis Henry, Knighton, Leicester.
Chatfield, William Charles, New Zealand.
Davey, Hon. Arthur, J.P., Godalming.
Hart, Sidney George, London.
Leetham, Sidney, York.
McArthur, Thomas, Liverpool.
Reid-Hyde, Major James, London.
Rogers, Henry, Birmingham.
Smith, Alfred, Keighley.
Stewart, Murray, London.
Turner, Sir Montagu Cornish, Romford.
Woodthorpe, John Brinkler, F.C.A., Vancouver, British Columbia.

The following candidates were balloted for and duly elected Fellows of the Society:—

Chiura, Captain T., Osaka, Japan.
Davies, Rev. John Llanfair, Pembrokeshire.
Dilke, Sir Charles Wentworth, Bt., Brighton.
Frank, Robert, London.
Manville, Edward, M.I.E.E., London.
Moore, Thomas Cartlich, J.P., Stoke-on-Trent.
Nisbet, James Richard, London.
Rait, George L., Surbiton.
Ridge, H. Mackenzie, M.I.M.M., London.
Smith, C. Thomas, Nottingham.
Snell, Sir John Francis Cleverton, M.Inst.C.E., London.
Warnes, Arthur Robert, Hull.

The paper read was—

THE ORGANISATION OF COMMERCIAL INTELLIGENCE.

By SIR WILLIAM H. CLARK, K.C.S.I., C.M.G.,

Comptroller-General of the Department of Overseas Trade (Development and Intelligence).

A notable effect of the crucial strain which has been placed on our economic resources by this huge and protracted war, has been an impulse towards a general stocktaking of our commercial and industrial methods, and more especially perhaps towards a critical examination

of the relations of the State and trade. The fabric of British industry has borne magnificently the heavy burden which has fallen upon it, and has presented a unique example of how the productive force of a nation can be diverted from its normal channels to the task of producing weapons of destruction and every class of military equipment; but the very thoroughness with which this has been achieved means that there are difficult times ahead of us before, when the war is over, industry can be fully restored to its normal functions. And anyone who looks forward at all cannot feel any serious doubt but that after the war there will be probably the fiercest competition for foreign trade which has been seen since our merchant adventurers first sailed the seas. The war has necessarily interfered to a very serious extent with overseas trade. Restrictions have had to be imposed upon export in order to secure the conservation of supplies and the prevention of goods reaching the enemy; in order to economise shipping, raw materials, and labour, and to divert them into the uses for which they are most required. As the war goes on, this process must become increasingly severe and trade grow more difficult; yet it will be vitally necessary for us to reconstitute and to develop our export trade as quickly as possible after the war, in order to strengthen our exchanges; and indeed the only certain way of replacing the wealth which has been destroyed must be for us, and for other nations alike, to increase and develop trade. Everyone, therefore, must recognise the vital importance of the whole commercial and industrial field being thoroughly explored, and of all steps being taken to secure that the wisest policy is pursued in relation to our trade, and the best machinery placed at its disposal. It is in regard to one element only in the problem that I propose to speak to-day—the question, namely, of what the State can do to assist trade, apart from the larger and more debateable issues of financial and commercial policy. I propose to discuss briefly what the organisation for this purpose should be, and to explain what has been and is being done by the Government in this country to strengthen and expand our machinery, so that it may be more fully capable of meeting our future needs.

Functions of a Commercial Intelligence Organisation.

What then are the proper functions of a Department of Overseas Trade—a department constituted simply and solely for the assistance of manufacturers and traders in promoting and extending their business? Such a department should clearly comprise a thorough and efficient machinery for the collection and dissemination of commercial information. It should be able to supply information and advice on all matters relating to overseas markets; on the conditions and prospects in them for British trade; and on the openings which they afford for business. It should possess comprehensive particulars of buyers and importers in overseas countries, classified according to the articles in which they deal, who may be likely to require British goods. It should be able to answer questions on foreign and colonial tariffs, and on all regulations affecting trade, such as customs regulations, and requirements relating to commercial travellers, investment of capital, and so on; and should have readily available commercial statistics bearing on all aspects of trade. It should be able to furnish reports on foreign competition in the various markets of the world, such reports being illustrated, wherever possible, with samples of the goods competing with British products. The question of competition should also be studied, not merely in the actual markets, but also from the point of view of the industrial and commercial methods and organisation of our principal commercial rivals in their own countries. It is clearly very important that our manufacturers and merchants should have at their disposal such information as can properly be obtained on what is being done in other countries, where business methods, as here, are constantly being tested and reviewed. It does not follow that our rivals' methods are necessarily better than our own; but it may safely be said that they will always repay study, and perhaps have not been sufficiently studied in the past. Then there is information relating to sources of supplies of raw materials for industry, an important branch of commercial intelligence which has been dealt with in this country mainly by the semi-official agency of the Imperial Institute, on whose work a paper was recently read by its Director before the Royal Society of Arts. An intelligence department must be prepared also to supply information bearing on industry at home as well as on markets overseas. It must know, if only for the purpose of distributing the information it collects, as much as it can about British manufacturers and the articles which they produce, and British merchants and the articles in which they are interested; and it must have an efficient machinery for the distribution of intelligence which, as I shall show later on, is not quite so simple a matter as it may sound.

But a Department of Overseas Trade must be more than merely an intelligence bureau; it must be able to take action, within certain necessary limits, in matters relating to the promotion of trade. It must be able to follow up the information it receives, and not only to bring it to the notice of manufacturers and traders, but to help them to take advantage of it. It may have other activities as well, such as the work undertaken by the Board of Trade in facilitating the participation of British manufacturers in international exhibitions, and in organising industrial fairs. In fact, most matters bearing on the promotion of trade will come within its orbit.

Type of Organisation Required.

In order to fulfil these functions it is necessary to have an organisation at home and corresponding services abroad, whose duty it is to feed the home organisation with material and to carry out its instructions. In deciding upon the best form of departmental organisation at home, certain difficulties occur at the outset which have their root in fundamental principles of administration. Experience has demonstrated, alike in public affairs or in the management of some great business, the danger of over-centralisation and the necessity for a reasonable division of the administrative machinery into departments; but difficulty arises when the matter to be dealt with falls partly within the proper ambit of two or more departments. In the case we are now considering, it is clear that the organisation at home must be in the closest possible touch with the trade and industry of the country concerned, and this points to its being part of whatever the Government Department may be which deals with commerce; but its activities are also very largely connected with foreign countries, and it depends largely on services in those countries, which suggests, on the other hand, that it might properly form part of the Department dealing with Foreign Affairs. The problem is one which is not peculiar to this country, though we have an additional complication in the extent of the British Empire, which has also to be covered, and has to be dealt with differently from foreign states. Various solutions have been adopted in different countries. Germany, curiously enough, considering the energetic interest which the German Government have always taken in trade, did not until a few months ago possess a ministry specially responsible for commercial affairs. Such matters were entrusted to a department of the Ministry of the Interior, but commercial intelligence appears to have been dealt with mainly by the Foreign Office, which controls the diplomatic and consular services. An Imperial Ministry of Economics has now been constituted, but it is doubtful whether any rearrangement of functions has been made in relation to foreign trade. France and the United States of America, on the other hand, have for some time past had special intelligence offices, which have been part of their respective Ministries of Commerce—the Bureau National de Commerce Extérieur in Paris, and the Bureau of Foreign and Domestic Commerce in Washington. In both cases also, while the diplomatic missions and consular services are under the control of their respective Foreign Offices, there is a special service of Commercial Attachés for commercial intelligence work in foreign countries, who, though attached to the diplomatic missions, are under the control of the Ministries of Commerce. In the United Kingdom the Board of Trade, nearly twenty years ago, instituted a Commercial Intelligence Branch of their Commercial Department, whose function was to be the collection and dissemination of commercial intelligence. The Branch was started on a very small scale in Whitehall, but shortly afterwards was transferred to the City, where it developed in due course into a large department. Overseas, in connection with Imperial trade, the Board, a few years after the creation of the Commercial Intelligence Branch, appointed officers of its own, known as Trade Commissioners, in the Dominions, who are assisted by Imperial Trade Correspondents stationed at various centres; but in foreign countries the Branch was dependent for the regular supply of commercial information on the Diplomatic Missions, the Commercial Attachés attached to those missions, and on the Consular Service. The Commercial Attaché and Consular Services, as well as the Diplomatic Missions, were under the control of the Foreign Office, though the Commercial Intelligence Branch was authorised to correspond direct with Consular Officers on commercial matters; and while much good work was done by both services, the arrangement had the obvious disadvantage that the department which was to utilise the information collected was not in a sufficiently close relationship with the officers who collected it. The system as a whole, in fact, had become unnecessarily complex; and the question of simplifying and improving it has been taken under examination not only by the departments concerned, but also by important commercial organisations, the Association

of Chambers of Commerce of the United Kingdom and the Federation of British Industries, who have both recently issued reports on the subject. A committee was appointed by the Foreign Office and the Board of Trade, under the chairmanship of Lord Faringdon, to inquire into the best form of organisation for promoting our foreign trade through representatives abroad, including the Consular Service; but it unfortunately failed to come to an agreement, and presented two reports which illustrate the difficulty, to which I have referred, of allocating responsibility for these functions. While both reports were in agreement that the control of the Commercial Attaché and Consular Services should be left to the Foreign Office, acting in close consultation with the Board of Trade as regards instructions and appointments, and that both services should be enlarged and improved, one report recommended that the department which in this country should have special charge of the promotion of overseas trade should be a department of the Board of Trade, and the other that it should be a department of the Foreign Office. Fortunately the Government have been able very quickly to cut the knot. The Foreign Office and Board of Trade took counsel on the matter, and decided that the only satisfactory solution would be to create a joint department, which should form a sort of bridge between them, and should be entrusted with the functions in respect of commercial intelligence and the development of overseas trade, which are so largely common to both.

Department of Overseas Trade (Development and Intelligence).

A new department has accordingly been brought into being, under the sonorous title of Department of Overseas Trade (Development and Intelligence). Parliamentary control over it is exercised through a new Parliamentary Secretary, who occupies the position both of Additional Parliamentary Secretary at the Board of Trade and of Additional Parliamentary Under-Secretary for Foreign Affairs. He is responsible to the President of the Board of Trade for all matters within the competence of that department, and responsible to the Secretary of State for Foreign Affairs for all matters concerning the Foreign Office. The official head of the department, who is styled the "Comptroller-General," is also an amphibious personality, appointed jointly by the President of the Board of Trade and the Secretary of State for Foreign Affairs. The appointment and control of the Trade Commissioners within the Empire rests as at present with the Board of Trade, and the appointment and control of the Commercial Attachés and Consular Officers with the Foreign Office; but the Board of Trade have entrusted to the new department the control of the Trade Commissioner Service, and the Foreign Office have handed over to it the control of the Commercial Attaché Service, and propose similarly to hand over the control of the Consular Service when premises can be found for the new department in close juxtaposition to its own offices. In the meantime, a further link is established by the Commercial and Consular Department of the Foreign Office being placed under the new Under-Secretary. The new department comprises the former Department of Commercial Intelligence of the Board of Trade, including the International Exhibitions Branch and the organisation of British Industries Fairs and sample exhibitions, and has taken over work and staff from the Foreign Office connected with its special functions. It has also incorporated the temporary War Trade Intelligence Department—a department which has collected an immense amount of information during the war—and certain sections of the work of the Foreign Trade Department of the Foreign Office. It is intended that there should be a constant interchange of staff between the new department and other departments of the Foreign Office and the Board of Trade, and that Commercial Attachés, Trade Commissioners and Consular Officers should serve in it for a period of training.

I am afraid that I have dealt with this aspect of the question in somewhat tedious detail, but it is really of fundamental importance. The scheme which I have just described is a comprehensive attempt to solve a problem which is not a new one, but which for some years past has been urged on the attention of H.M. Government by the commercial and industrial community. Their criticisms have been specially directed against the duality of the former system, under which, while the direction of the Commercial Attaché and Consular Services rested with the Foreign Office, the utilisation of the fruits of their commercial work lay with the Board of Trade. Under the new scheme the direction of the commercial work of the foreign services and the distribution of the intelligence collected by them will be dealt with by a single department, and as the same department will also direct the Trade Commissioner Service within the Empire,

uniformity of policy will be secured in respect of overseas trade as a whole. The new department is authorised to take action arising out of its commercial intelligence work in connection with the promotion of overseas trade, subject of course to the exceptions that the larger issues of commercial and industrial policy are, and must remain, the concern of the Board of Trade, and that all matters affecting relations with foreign Powers are, and must remain, the concern of the Foreign Office.

Organisation of the Department.

In organising the Department we have had to contend with the usual difficulties arising out of the war—shortage of staff and the difficulty of securing adequate accommodation. The general framework, however, has been laid down, and the gaps can easily be filled up later on. The department has been constituted in three main divisions—the Overseas Division, the United Kingdom Division, and the Exhibitions Division. Of these the two first are the divisions which deal with the collection and distribution of commercial intelligence. The Overseas Division, which deals primarily with all correspondence from abroad and especially with correspondence with the Commercial Attachés, Consuls, and Trade Commissioners, and which is responsible for the administrative work connected with the Commercial Attaché and Trade Commissioner Services, has been divided up into a number of geographical sections and subsections, which can be added to as the work and the staff develop. The United Kingdom Division, which handles the correspondence with firms in this country and the distribution of commercial information, has been divided up into sections and subsections according to groups of trades, together with special sections for tariffs, statistics, transport, finance, etc. The organisation, in fact, aims at specialisation, and enables us to take advantage of the special knowledge or qualifications possessed by particular officers, in relation either to particular markets or to particular industries. The Exhibitions Division deals with the organisation of the British Industries Fairs, sample exhibitions, and so on, of which I shall have something to say later on. We possess a commercial reference library, where we file quantities of British and foreign trade papers and books of reference of all kinds, a sample room for the display of samples collected from abroad, and an inquiry room where oral inquiries can be made. So much for the general outlines of the organisation at home.

Overseas Services. The Trade Commissioner Service.

If the work of a department concerned with overseas trade is to be of value, it is clearly essential that it should have an efficient network of correspondents throughout the world. I have already alluded to our overseas services, the Trade Commissioners, and the Imperial Trade Correspondents within the Empire, and the Commercial Attachés and Consular Officers in foreign countries, but it is necessary to describe their organisation and work in rather more detail. The Trade Commissioner Service is of comparatively recent origin, having been instituted by the present Prime Minister when President of the Board of Trade after the Imperial Conference of 1907. Four Trade Commissioners were then appointed—one for Canada and Newfoundland, and one each for Australia, New Zealand, and South Africa, each having the assistance of a number of Imperial Trade Correspondents stationed in various districts of the Dominion concerned. The Commissioners' functions are to keep in close touch with the Government and State authorities in the Dominions; to visit the principal commercial centres; to watch and report upon foreign competition, on financial and trade conditions, and new legislation affecting trade; to make an annual general report on the conditions and prospects of trade in their areas; and to furnish special reports and monographs on particular questions which are likely to be of interest to British trade. They are also expected to supply a regular flow of commercial information of all kinds; to maintain an active correspondence with firms in the United Kingdom who wish to extend their trade with the Dominions; and to give all possible assistance to representatives of British firms who may visit their areas. An encouraging testimony to the value of the work of the service is to be found in the steadily growing volume of their work, and in the enhanced interest taken by the commercial community in their periodical visits to this country. Their work was investigated by the Dominions Royal Commission during their tour through the Empire, and the Commission reported strongly in favour of an extension of the service. The Board of Trade had simultaneously been engaged on a scheme for this purpose, and it has now been decided to increase the number from four to fifteen or sixteen. So far as the allocation of posts in the enlarged service has been decided, it is proposed that four shall be stationed at important centres in Canada; two in Australia;

one in New Zealand; two in South Africa; two in India; one in the West Indies; one in the Straits Settlements, and one will be available in the department for special service. With the assistance of a selection committee, appointments have now been made in addition to the four officers who already hold posts in the service; and an officer is already on his way to India to open up the office in that important area. It has also been arranged, after discussion at the Imperial War Conference of last year, that the Trade Commissioner in any particular area shall also be at the disposal of any of the Dominions or of India which may not have representatives of their own in the area concerned—in other words, it will be part of his duty to promote inter-imperial trade as well as the trade of the United Kingdom.

The Commercial Attachés.

In foreign countries there has been for some years, in addition to the Consular Service, a service of Commercial Attachés attached to certain embassies and legations. The service, prior to the war, comprised eight officers, several of whom had charge of very large and unwieldy areas; a single officer, for instance, had to cover the whole of Austria-Hungary, Italy and Greece, and there was only one officer for countries so vast as Russia or China. The Commercial Attachés, therefore, had in many cases to contend with very considerable difficulties. The Foreign Office now propose to develop the service on a thoroughly comprehensive scale. A committee was appointed last year, which has drawn up a scheme to cover all foreign countries of commercial importance; to provide the Commercial Attachés at the principal posts with assistants; to equip them with sufficient office allowances for the provision of adequate staff; and generally to place the service on a strong and suitable footing. A first instalment of the scheme has been sanctioned, and will enable us to proceed at once with the work of filling the more important posts. A selection committee has been appointed to review candidates and to make recommendations to the Secretary of State, and has already entered upon its duties.

The efficiency of our commercial intelligence system, and of trade representation generally in foreign countries, will in future depend to a very large extent upon the Commercial Attaché. While it is very desirable that he should not be too much absorbed in the work of the embassy or legation to which he is attached, the head of the mission will naturally turn to him for advice on commercial questions. It will also be part of his duties to superintend the commercial work of the Consular Officers in his area; he will often have to call upon them for information, and much of their work will thus tend to be focussed through him, so that he will be able to exercise a considerable influence upon it. He will have to deal with the larger inquiries affecting the trade of the country as a whole; and to furnish an annual report and monographs on special topics. An important part of his functions will be to keep in close touch with British Chambers of Commerce in foreign countries, and with the British commercial community generally, and to assist them in every possible way; and we hope that it will become increasingly the practice of British business men who visit foreign countries to call upon the Commercial Attaché and to maintain close relations with him.

Generally speaking, both in the case of the Trade Commissioners and Commercial Attachés, the efficiency of the services must depend largely on the initiative, energy, and experience of the officers themselves. Instructions are being prepared for them, but no instructions, however comprehensive, can in themselves enable their recipients to cover satisfactorily the whole field of their activities. The rest must be left, in part, as I have said, to their own initiative and in part to the guidance which they should receive through constant communication with the Department and through the relationships between them and the business community. In developing these latter, we have found that it is very useful to bring officers home at regular intervals and to arrange tours for them—with most valuable co-operation from Chambers of Commerce—through the principal commercial and industrial centres of the United Kingdom. This has been the practice for some time past, and has been attended with very good results. The demand for interviews is so considerable that the time spent in one of these tours now amounts to over four months, and the officer has to undertake some hundreds of interviews, besides giving addresses to Chambers of Commerce, Trade Associations, and so on. At the same time, he takes the opportunity of inspecting works and factories, and familiarising himself with the products and methods of British manufacturers.

The Consular Service.

The question of strengthening the Consular Service by a revision of the present posts and pay, is also under examination by the same

committee which drew up the scheme for the Commercial Attaché Service, and I hope that the result will be to remove some of the disabilities under which the service has laboured in the past. More posts are required and a more generous provision to meet the cost of residence in certain countries. It is not possible for me, in the course of this brief survey, to enter on any detailed discussion of the constitution and working of the service, but I would ask you not to accept too hurriedly the criticism which has been somewhat freely directed against it from time to time. Much of this criticism has not been fair in itself, and it has failed to take into account the difficulties with which many Consular Officers have had to contend. A large proportion of the officers, in my experience, take a genuine interest in their commercial work, and expend much pains on it; and supply us with really practical and useful information. With more systematic direction and guidance in their work, I see no reason why very good results should not be obtained.

Special Investigations of Overseas Markets.

Closely connected with the question of the overseas services is that of the expert investigation of markets abroad. However efficient the permanent official representative may be, it will frequently be necessary to supplement the intelligence which he sends home by special inquiries. All our representatives cannot be men who have had actual business experience, and even if they do possess such experience in one or another class of business, they would not be in a position to furnish reports as experts upon all of the large variety of trades with which they may be concerned. On the other hand, experience has shown that expert investigation of markets is becoming more and more necessary. The Board of Trade have frequently in the past despatched special commissioners to investigate particular markets and to report upon the conditions and prospects in them for British trade. Such missions have been sent to South and Central America, Canada, Australia, South Africa, Japan, Persia, China, and to Russia. In these cases the commissioner has been charged with the duty of reporting on the prospects of British trade as a whole, but the growing intensity of competition between manufacturers of various classes of commodities for the trade of the large consuming markets has made it increasingly desirable that the market should be surveyed in respect of the openings for any particular industry by men with specialised knowledge of the conditions of the industry in this country. During last year three technical investigators were sent by the Board of Trade to Spain, charged with making inquiries in respect of certain limited ranges of goods, one investigator taking the electrical trade, another marine engineering, and the third the iron, steel and engineering industries. The reports have now been received, and there seems little doubt that the method pursued has been justified. It is a method, I may say, which has been adopted to a very considerable extent in the United States, where the Bureau of Foreign and Domestic Commerce, in addition to having Commercial Attachés at certain centres abroad, has in the last few years conducted a number of specific trade investigations in respect of various industries in several markets of the world. The Board of Trade last year carried the matter a little further, and took up, with the assistance of their Advisory Committee on Commercial Intelligence, the question of co-operation with the trades themselves in joint investigations of particular trades in overseas markets. Such investigations had been urgently pressed by some of H.M. Trade Commissioners and Commercial Attachés, with a view to cultivating markets for trade after the war. H.M. Commercial Attaché in the Argentine especially urged that, in order to make these investigations effective, it was desirable that an investigator should be selected by the trades concerned, but that he should go out with the support and assistance of Government. A special sub-committee of the Advisory Committee was appointed to investigate the matter, and to take evidence from trades which seemed especially suitable. They recommended that the Board of Trade should actively take up the question of facilitating the formation of export associations of manufacturers, especially with a view to despatch by such associations of expert investigators to approved overseas markets, and that Government should contribute to the cost of the inquiries. The Board of Trade accepted the report, and one such investigation has already been arranged for. The Department of Overseas Trade has been in communication with representative associations in the jewellery, silverware, and electro-plate trades, and as a result arrangements have been made for a joint investigation of the South American markets, the cost of which is being defrayed in part by the trades and in part by H.M. Government. The associations concerned have done us the compliment of selecting an officer of the Department for the inquiry who had had several years'

experience in the trade before entering Government service; and he has spent some months in studying products and methods of manufacture of the firms concerned before starting on his tour. He will carry samples in order to show what is being made in this country, and will collect samples of competitive goods in the South American market. This scheme has been the cause of a certain amount of misapprehension and criticism, on the ground that it is an undue interference with individual enterprise, and one which may result in the deflection of trade from its normal channels. There is, of course, no such intention on the part of the Government, and I see no reason to suppose that it is likely to occur. The investigator will not book orders. The whole object of the inquiry is to place in the hands of British manufacturers accurate information as to the types of goods most in demand and the conditions required by their customers, and thus to facilitate a ready adaptation of their patterns and methods to meet the varying requirements of different markets. The special merit of the scheme is the close co-operation involved between Government and the manufacturers concerned. Such co-operation, it seems to me, is far the most efficacious method of securing that the work will be directed on lines which will be most practical and useful to the trade.

Relations with the Commercial Community.

Not the least important in fact of the problems which a commercial intelligence department has to solve, is how it shall maintain the closest possible touch and secure the most effective co-operation with the commercial community which it is to serve. Such touch is essential in order that the department may know how best to direct its overseas services, and how to distribute the commercial intelligence which it collects from all parts of the world. With this object in view, an advisory committee of business men is shortly to be appointed to assist the Department of Overseas Trade in its work. In constituting this committee, the Foreign Office and the Board of Trade hope to reconcile what may appear at first sight to be almost conflicting requirements—namely, that on the one hand the committee should be as representative as possible of the many aspects of British trade, while on the other hand it should not be so large as to interfere with practical and efficient working, since we hope that it will meet frequently and take a real part in the work of the Department. But even more important, perhaps, than the best and most willing of advisers are the constantly growing relationships with the business world which arise out of the work of the Department. I am glad to say that the number of inquiries which were received by the former Department of Commercial Intelligence of the Board of Trade increased rapidly of late years, and I hope that with the larger scope of the new Department the process will continue even more vigorously. Such inquiries constitute a most informative record of the needs of particular firms; of the classes of goods which they manufacture, and of the markets in which they are interested. All such inquiries are indexed under the name of the firm, and we are gradually building up in this way a comprehensive and detailed index of British manufacturers and their products. This is now being supplemented and made more complete by circularising the trades concerned, and in due course it will be compiled in a form which will enable it to be placed at the disposal of our Commercial Attachés and Trade Commissioners overseas, so that, in dealing with local inquiries, they may have an authentic record of British manufacturers.

Methods of Distribution.

In addition, however, to supplying information in reply to inquiries which may be received from the outside, a properly-equipped commercial intelligence department must also have its machinery for the distribution of information upon its own initiative. The object as regards a certain proportion of such information is merely to secure as much publicity as possible, but much of it is necessarily confidential, so that machinery is required which, while safeguarding the confidential nature of the intelligence, will not prevent its reaching freely those to whom it will be of interest and value in the promotion of their trade. For the dissemination of the more public class of information, we have the *Board of Trade Journal*, a weekly paper which was formerly edited in the Department of Commercial Intelligence of the Board of Trade. It has now been placed on a much more comprehensive footing, and, by the introduction of special articles and other more readable matter than was thought necessary in the former somewhat austere paper, will, I have little doubt, secure a much larger circulation, and will be a really valuable vehicle for the distribution of our material.

For the distribution of confidential information we have two channels. The first of these,

which is known as "Form K," we owe to the ingenuity of the Foreign Trade Department of the Foreign Office, who have now handed it over to us. It is a system for supplying traders and manufacturers with information in regard to possible importers in certain foreign countries of goods of British manufacture. Such information lends itself to collection within the compass of a form, which is sent out to all Consular Officers in the countries concerned. The form ensures uniformity and thoroughness in the compilation of the reports and greatly facilitates dissemination. The items of the form comprise the main preliminary particulars which it is necessary for a firm in this country to know who are contemplating opening up business with an importer's house abroad—such as the articles in which the house is interested; their European references; the general nature of their business, and the terms on which they trade. The distribution has been arranged in co-operation with the Association of Chambers of Commerce and the Federation of British Industries, who have readily given their help and have undertaken the responsibility of communicating the information to interested firms. Firms apply to receive the reports through their representative Chamber of Commerce or Trade Association, and have to be approved by the Department. There are now over 10,000 traders in receipt of the intelligence distributed by these means.

The second channel of confidential distribution is known as the Special Register. It is kept in the Department for the purpose of passing on to firms confidential intelligence of a more general scope than that provided under Form K. While Form K, as I have explained, is confined to lists of firms in certain foreign countries, with the relevant information relating to them, the intelligence supplied through the Special Register includes specific openings for trade abroad in all parts of the world, reports on foreign competition, reports on various industries in countries overseas, and on general financial and commercial conditions. Reports on particular trades or markets which are obtained from time to time as the result of special commercial missions, are also circulated to firms on the Special Register. The Department charges a small annual fee for the service. In spite of the hampering effect of the war on overseas trade, it is satisfactory to find that the number of firms on the Register steadily increases, and is now between 3,000 and 4,000. I should be glad, however, to see it very much larger.

International Exhibitions and Fairs.

There is only one other matter on which I should like to touch very briefly—namely, the use of exhibitions and fairs as a means of promoting overseas trade and the functions of Government in connection with them. A great deal of attention has been given to this matter by the Board of Trade in recent years, and its close relationship with commercial intelligence has been recognised by the incorporation last year of the Board's International Exhibitions Branch in the former Department of Commercial Intelligence, and by the Department being entrusted with the organisation of the British Industries Fairs. The International Exhibitions Branch was established some few years before the war in order to facilitate the participation of British manufacturers in foreign exhibitions, to protect their interests, and generally to superintend the formation of the British section; and though the work has, of course, been in abeyance during the war, I have no doubt that it will revive afterwards. Exhibitions and fairs, though they differ markedly in scope and externals, have this in common—that they are both methods of bringing buyers and manufacturers together. When an international exhibition is held in an overseas country, the British manufacturer sends his goods there in order that they may be seen by the buyer in that country; the object of a fair in the United Kingdom is to secure the same end by bringing the buyer from abroad to see the goods set out in the fair here. Fairs, however, are organisations much more definitely for business purposes than exhibitions; they are usually open only to the trade, and producers exhibit with the object of transacting business and of placing orders during the currency of the fair with the wholesale buyers. All the costly accessories of international exhibitions can therefore be dispensed with. The essential principle of such fairs is that business is done entirely by sample; and consequently they are most suitable for goods which can be displayed conveniently in this way, so that firms can show their products within the comparatively narrow space of a stall where they can be inspected and where orders can be placed by trade buyers. The classic example of such fairs in the past has been the well-known Leipzig Fair. In this country they are directly a product of the war. They arose out of the efforts of the former Commercial Intelligence Branch of the Board of Trade, shortly after the outbreak of war, to assist British manufacturers in taking up lines of goods in which German competition had hitherto

been notably successful in this country, and to assist buyers who were in difficulties owing to their previously having been dependent for the commodities required in their business on supplies from enemy sources. In order to bring possible producers and buyers into touch, the Branch arranged a series of exchange meetings covering a number of trades; and the logical outcome of these was the first British Industries Fair, which was organised by the Board of Trade in 1915. It was the first fair of its type, so far as I know, to be promoted on at all a large scale in England, and I should like to take this opportunity of paying a tribute to the enterprise of the small band of Government officials who, without previous experience, undertook and successfully carried through its organisation. Since then the Fair has become an annual institution, the exhibitors at the first Fair having petitioned the Board to continue the work; and the Fair for 1918 will be held in a few days from now. The number of trades which can be included has had to be severely restricted in order to avoid any interference with the paramount necessity of the production of munitions, so that the Fair now only comprises four trades—fancy goods; china, glassware and earthenware; printing and stationery; and toys—but after the war there will be unquestionably a rapid development.

Government agency, of course, is not an essential to the organisation of a fair; for instance, since our fair was instituted, the Corporation of Glasgow have also promoted one, under the auspices and with the support of the Board of Trade, embracing certain trades not included in the London Fair; and in the first year after the war Birmingham proposes to follow their example in regard to the trades centred in their city. But Government management undoubtedly has its advantages, and I have no doubt that the London Fair will continue to be organised by the Department of Overseas Trade. We run our fair on a strictly business footing and without any grant from the Treasury, but we are able to get the cost to the exhibitor of his accommodation down to a tolerably low level, and thus to make it easier for the smaller firms to participate.

Fairs are unquestionably of great value in the development of trade. At Leipzig, before the war, the number of exhibitors had totalled 4,000, while the Fair was attended by many thousands of buyers from all parts of the world; and German trade in a long list of articles has been immensely benefited by these Fairs, at which the buyers sometimes placed orders covering their entire requirements for the year. Our fair comprises at present something over 400 exhibitors, but as the Leipzig Fair has been in existence since the Middle Ages and ours is but a three-year-old bantling, and those years of war, we need not despair of making good the difference. The Germans, at any rate, are becoming nervous about the future. They have made strenuous efforts to maintain the continuity of the Leipzig Fair throughout the war, and it was announced, not long ago, that it is to receive a subsidy of £50,000 per annum in order to help it to make good its former prestige. Our fairs, as I have said, are self-supporting; and I think we may take this anxiety on the part of the enemy as something of a compliment to ourselves and to our Allies, the French, who have followed our example in organising similar enterprises at Lyons and Paris.

Sample Exhibitions.

The exhibition method is also of value for illustrating foreign competition and the requirements of a particular market. We have a sample room at the Department of Overseas Trade, where we have at present a considerable collection of samples of German and Austrian goods which were competing with British goods in different parts of the world. We endeavour to keep these collections constantly up to date, and when we are able to form sufficiently comprehensive exhibits in particular lines of goods, we arrange for them to be shown in the industrial centres of the United Kingdom where they will be specially of interest. A series of exhibitions of this kind was held a little over a year ago, and the exhibits subsequently visited Canada at the request of the Canadian Government. Experience has proved that this class of work is of particular value to manufacturers, who are allowed to borrow the samples with a view to making a thorough technical examination of them at their works. We have recently sent out instructions to our officers overseas to collect samples of hardware and textiles in certain important markets, and these when received will be exhibited in the same way. The Department has also formed an extensive collection of foreign manufacturers' catalogues, mainly German and Austrian, which throw a valuable light on their competitive products. These catalogues are constantly on loan with British manufacturers.

Conclusion.

I have endeavoured, in putting before you this survey of our commercial intelligence

system, to avoid so far as possible wearisome detail and only to give you a general outline of our work and aims. Our organisation, of course, is very far from perfect; no small part, indeed, of the interest of the matter lies in there being always new methods to be investigated and new types of inquiry to be taken up. But if, as we hope, the foundations have now been laid on sound lines, the rest will follow quickly enough, provided the work is carried on with intelligence and energy, and provided always that we do not forget the important truth —that a Government department cannot help the commercial community efficiently unless it works in the closest co-operation with them, and not only, according to its own lights, on their behalf.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Lord Faringdon), in opening the discussion, said that he had listened to the paper with the greatest interest. The subject was one with which he was fairly familiar, as he had been the chairman of the Departmental Committee that considered the question when there was a little friction between the Foreign Office and the Board of Trade. He was glad to think that that friction had been disposed of by the happy arrangement which the Government had made, and arising out of that came the new and important Department of Overseas Trade. It was certain that the keenness of competition after the war in connection with trade would be greater than anything that had been experienced in the past, and it was essential that the people of this country should have the most thorough knowledge it was possible to obtain of all conditions affecting trade both at home and abroad. There was no doubt room for improvement in our Consular Service, and also in the home service, in connection with the information which was available, but was frequently not taken advantage of. When the information arrived it was essential that it should be classified and put into such order that it was readily available for those who required it. He had repeatedly found that at the Foreign Office and at the Board of Trade a mass of information was obtainable upon different subjects, but it was not readily available; it had to be unearthed and put into shape before it was sufficiently intelligible for any one who was taking up a new subject to understand it. He thought the new Department of Overseas Trade would have a great deal to say with regard to the arrangement of the information that came before it, and he hoped that the traders, the manufacturers, and the merchants of this country would take full advantage of the Department. There was a disposition on the part of a certain number of people to say that they could obtain all the information that Government Departments possessed through their foreign correspondents, and the very people who were crying out against what they called the inefficient Consular Service of this country were those who, as a rule, were the very last to go to a Government Department for any information. It had been his duty to go to several countries abroad, on behalf of the Government, since the war began, and he had been struck, not by the inefficiency but by the wonderful efficiency of the Consular Offices that he had visited. There might be complaints of the British Consular Service, but those complaints were not limited to this country; precisely the same kind of complaints were made in every country. The people of the United States, Germany and France were continually complaining of their Consular Services, and, after all, that was a very good sign. If one was satisfied with anything it often meant that one was not taking very much interest in the subject and was going backwards instead of forwards. The appointment of the Commercial Attachés and the Trade Commissioners that had been referred to in the paper was bound to have a good and stimulating effect upon trade. The happy-go-lucky conditions of the past had to be abandoned, and more thorough methods must be introduced. In the future there would have to be less time for recreation and more time devoted to work; and, above all, it was absolutely essential that in the future modern languages should be cultivated to a greater extent than had hitherto been the case. It must be remembered that it was not only British trade that had to be considered—it was the trade of the Empire, and he was glad to note that the Trade Commissioners were not only going to look after the trade of Great Britain but were going to devote their attention to the trade of the Empire as a whole. Whatever the Government might do for the trader would only be in the nature of assistance; the British trader had depended in the past upon individual effort, and it was upon that individual effort that British trade would have largely to depend in the future.

SIR ALGERNON FIRTH, Bt. (President of the Association of Chambers of Commerce of the United Kingdom), said it was necessary at the present time for all those interested in trade to do their utmost to make the new Department of Overseas Trade a success, to still the voice of criticism and to render all the assistance they could to the Department. It should be the work of that Department to find out where this country was not getting its share of the trade in any individual article; it should go through the imports of certain countries where the articles were supplied to a large extent by foreigners, and this country was not getting a fair share of the business. Then it should lay the facts before those interested in the trade in this country, and, with the assistance of the new Trade Development Branch of the Board of Trade, some machinery should be devised whereby this country might obtain its share of the business. British traders did not look for a monopoly in any market. Possibly they had been too individualistic

in their business. Personally he was a firm believer in individuality, but also in co-operation; and if individual effort failed in any direction then the individuals concerned should meet together and see if by a combination of brains and effort they could arive at the desired result. In that way, with the assistance of the Department of Overseas Trade, success would be assured. He hoped also that the Department was going to help the traders of this country to obtain business which their German and other rivals had previously been able to obtain owing to Government assistance and the banking assistance they had been able to command. If the Government, the bankers, and the traders of this country would pull together in a similar way, a great deal more business would certainly be obtained. With regard to the debate that had taken place in the House of Commons on the previous evening on the subject of the Department of Overseas Trade, he strongly deprecated the cavilling that had taken place about the amount to be spent on the salaries of the staff of the Department. If brains were required they must be paid for, and the scale of salaries mentioned in the debate as the proposed payment of the heads of the Department was in his opinion totally inadequate. The men who undertook the responsibility of such a Department, and were supposed to supply initiative and not merely to perform routine work, ought to be paid on a very different scale from that mentioned in the debate.

Mr. Philip B. Kennedy (Commercial Attaché, United States Embassy) said that, having been for two years the American Commercial Attaché in Australia, he took a great interest in watching the development of the British Overseas Trade Department. There were two very significant features in its development: first, that all the activity relating to foreign trade had been brought under one Governmental head; and, secondly, that that action had been correlated with the business interests. In Washington there was still a gap between the Department of State and the Department of Commerce—the Commercial Attachés and the Consuls not being directly connected. There had been a considerable amount of personal co-operation between the two Departments, but he thought there was a very sound reason why it was desirable to have one common head if that was possible. The Consuls in the United States sent in their reports to the Department of State, those reports being published and distributed through the Bureau of Foreign and Domestic Commerce, and sometimes there was delay in getting them through. One could not always be in touch with men who were reporting to another Department, and there was sometimes duplication of effort. Before he entered the Commercial Attaché Service of the United States he had been for two or three years a member of the Foreign Trade Committee of the Merchants' Association of New York, and he had felt then that the members of that Committee did not always give the weight they should give to the services rendered to them by the Consular Service, so that when he entered the Commercial Attaché Service he felt doubtful whether he would be able to help them in any way. That feeling, however, had entirely disappeared, and he had found that business men were quite ready to accept any assistance that could be given to them. The United States Commercial Attachés were supposed both to follow general tendencies and also to be of specific and concrete assistance. During the war they had not had much time to devote to concrete problems, but after the war their object would be to give assistance to individual firms, and if that was to be done the Government officials must adopt the same attitude towards trade as the private business man did.

Mr. Ernest Benn said the connection between Government Departments and the commercial community of the country had never been very close, and personally he very heartily welcomed the evident desire of the new Department of Overseas Trade to take into its confidence the traders and commercial men whom it had to serve. He thought the author and his staff were to be congratulated on having done so much in such a short time to build up the new Department, but he hoped there would be no feeling that the work was finished. The author had mentioned the subject of special inquiries on behalf of special industries in special markets, which was a development of the utmost importance; and he did not think the Department should be satisfied with their work until they had arranged for an inquiry on behalf of each industry in each market, always bearing in mind that those inquiries must be made by men thoroughly conversant with the technique of the industry with which they were dealing. Sir Arthur Steel-Maitland had recently mentioned that the Overseas Trade Department was considering the setting up of Trade Committees to advise the Department on the requirements of each trade, and he hoped that those Committees would soon be formed. He thought the Department would have to watch very carefully the reconstruction process that was going on in industry at the present time, and should endeavour to make its work conform with the rearrangements that would undoubtedly be made in the near future in British trade. Traders were now beginning to realise the need of co-operating, and he thought that as a result of the Whitley Report some movement would come in which traders would realise that there were common interests between competitors and between capital and labour, the promotion of which was the best way to serve the individual interests of everyone. It was with those common interests in a trade that the new Department should especially concern itself. It would be a great advantage if the various activities of the Government could be in some way co-ordinated, so that a trade would not be confused, as it was at present, by having to deal

with a dozen different Government Departments. For instance, the National Pottery Council was looking to the Government for assistance in many directions, and it had to go to the Department of Overseas Trade for information with regard to overseas trade, to the Department of Scientific Research for help in research, to the Home Office for legislation with regard to Factory Acts, and to the Board of Education for technical education. He hoped that out of the new Department there would arise in the future some attempt to co-ordinate the relations between the Government and trade, so that on the one hand there would be perhaps a Minister of Commerce and on the other a Trade Authority in each trade. The author had not dealt with the subject of labour, but he thought the new Department had a great responsibility in that matter. Labour was now asking for a share in the control of industry. In his opinion it could never have any real share in the control of individual businesses, but it could co-operate with employers in negotiations with a Department such as the Overseas Trade Department, which might be a means of satisfying the very proper aspiration of labour to share in the higher direction of industry. If some way could be found whereby matters such as the special inquiries referred to could be negotiated, not only with capital but also with labour, it might help in the problem of industrial unrest.

Mr. G. Booth Heming said it was very gratifying to commercial men to know that they had now a Department which was going to give the whole of its energies to overseas trade. In the past manufacturers had always acted upon the conservative lines that what suited them or the people at home must of necessity suit the foreigner; but the great thing it was necessary for them to do was first to ascertain a want and then supply it. Another hindrance to British trade was the inefficiency of the Consular Service. About seven-tenths of the Consuls were foreigners, who could not be expected to take very much interest in British commerce, and if that commerce was to be increased there must be British representatives established abroad, who would obtain the necessary information and give it to traders at home, so that they could supply the goods that were required. It was always held that trade followed the flag, and that was quite true many years ago, before this country encountered competitors; but the practice now was for trade to follow the bank. The joint-stock banks of this country did nothing to help the struggling manufacturer. In Germany the Consulate and the Embassy were in touch with one another, and after they had settled themselves in a particular town the Deutsche Bank, or some other bank, also established a branch in that place. Then the bank would go to a particular firm and ask if it could assist them in any way, and eventually it would obtain a good deal of control over the business. The information was immediately sent home to Germany, with the result that a firm would be opened under a German name, and would eventually take over the business, supported by the Embassy, the Consulate and the bank, and also the home Government. The British Government, on the other hand, had done nothing for commercial men, and it was a very lengthy business to obtain any information from the Foreign Office with regard to trade.

Mr. James Munford wished to ask the author whether candidates for employment in the Overseas Trade Department would be required to have a university degree, and also whether women would be eligible for appointments in the Department at home. He knew of a case where a well-educated and experienced practical farmer had been refused a position at the Board of Agriculture because he did not possess a university degree.

Sir William H. Clark, K.C.S.I., C.M.G., in replying to the discussion, said that the Department was fully conscious of the difficulty of the work it had to do. The extent of the programme before it had been foreshadowed in some of the speeches that had been made that afternoon. Mr. Benn had referred to possible activities which would involve a very large amount of work. He had said, for instance, that the Department ought to be able sooner or later to make expert inquiries into practically every industry and every market. That was a counsel of perfection, and would be very difficult to accomplish. The question of expense had also to be considered, and he felt that such inquiries were a matter in which the trade ought to bear part of the expense. The Treasury was prepared to be generous, and he was grateful to Sir Algernon Firth for emphasising the necessity for liberal expenditure in connection with the Department, but he thought the State could hardly be expected to undertake the whole cost of the inquiries in question. He agreed with Mr. Benn as to the desirability of having one Government Department which could co-ordinate the relations of the commercial community with the Government. During the war there had been a very large increase in Government Departments controlling and dealing with trade, and it had been very difficult for traders to know to whom they ought to apply in matters affecting their trade; but his Department had tried to help in that respect, and had constantly borne in mind the importance of there being a Department to which a trader could always go for advice and information upon any matter, including, as Mr. Benn suggested, Governmental questions. Mr. Benn had also referred to the question of consulting labour as well as manufacturing and commercial interests. This was a matter that the Department was considering. It was clearly one of very considerable difficulty, and he could not say anything definite about it as yet. Mr. Booth Heming had spoken very severely about the Consular Service, but did not go into detail with regard to his charges against that Service. It was hoped that it might be improved by starting from the bottom and giving a better business training to new recruits, but it was not fair to say that it was

a generally inefficient Service. As the Chairman had pointed out, the same complaints were met with in every other country; they were even to be found in German papers, although the German Service had always been held up before this country as a model. The British Service had a far larger proportion of paid to unpaid Consuls than any other country in the world, but the unpaid Consuls could not be dispensed with altogether; nor was it necessary, as in many small places their duties were entirely uncommercial. He agreed that where it was possible to obtain an Englishman to act as Consul it was desirable to do so, but it could not always be done. In reply to Mr. Munford, a university degree was not essential in the case of candidates for employment in the Department, and a good many women were already employed there.

On the motion of the CHAIRMAN, a vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

OBITUARY.

SIR SWIRE SMITH, LL.D., M.P.—Sir Swire Smith died in London on March 16th, after a slight operation, at the age of seventy-six. He was born at Keighley, and educated in his native town and at Wesley College, Sheffield. Throughout his life he devoted himself to the cause of technical education. When twenty-four years old he was appointed secretary to the building committee of Keighley Institute, and took a prominent part in the work of reorganisation which led to the institute's remarkable success. So great was this that Professor Huxley once declared that Keighley had gone far to solve the problem of technical education; and the late Duke of Devonshire, when speaking of the National Association for the Promotion of Technical and Secondary Education, said that, in brief, its object was to induce the rest of the country to follow the example of Keighley.

Sir Swire Smith travelled a great deal on the Continent and in America to study methods of technical education. In 1881 he was appointed representative of the woollen industries on the Royal Commission on Technical Education, and he subsequently became a member of the committee of the National Association for Technical Education already referred to. He also took much interest in the work of the Exhibitions Branch of the Board of Trade.

In 1888 he read before the Royal Society of Arts a paper on "The Technical Education Bill," for which he received a silver medal, and in 1897 another on evening schools. In 1892 he was elected a member of the Society. His last appearance here was made as recently as February 13th, when he took part in the discussion on Lord Leverhulme's paper "'Zero' of Capital and Labour."

He received the honour of knighthood in 1898, and since 1915 he represented the Keighley Division of Yorkshire in the House of Commons.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

APRIL 10.—W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., will preside.

APRIL 17.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

APRIL 24.—MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons." The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India." The RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., will preside.

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana."

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." Three Lectures.

April 8, 15, 22.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 22, 1918.

No. 3410. MARCH 29, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,410. VOL. LXVI.

FRIDAY, MARCH 29, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

COLONIAL SECTION.

A meeting of the Colonial Section was held on Tuesday, March 5th, 1918; SIR OWEN PHILIPPS, K.C.M.G., M.P., in the chair.

THE CHAIRMAN, in introducing the author of the paper, said that Portugal was Great Britain's very oldest ally. The friendship of the two countries was deeply rooted in their history, and was intensified by the fact that just two years ago, *i.e.* on March 9th, 1916, Portugal joined with the other Allies in the war against Germany. The Portuguese soldiers had played a gallant part not only in France but also in the East African campaign, which was now on the verge of a successful termination. He could not refrain from recalling the great deeds of Portugal in days gone by, when, in the fifteenth century, her famous sailors Bartolomew Dias and Vasco da Gama were sent by their enlightened Prince, Henry the Navigator, into unknown and uncharted seas and founded a vast colonial empire in South America, Africa and the East. As chairman of the Royal Mail Steam Packet Company and of the Union-Castle Line, he might say that the former company had had a long and intimate association with Portugal and her colonial empire, its contracts for the conveyance of mails between Lisbon and Brazil dating back to the year 1850. During the present war the company had carried large numbers of Portuguese woodcutters, who had been employed in felling trees in the United Kingdom for war purposes, thus setting free for the conveyance of food a great deal of shipping which would otherwise have to be employed in the conveyance of timber to this country. The Union-Castle Line had also had a long and close connection with the Portuguese colonial empire on the East Coast of Africa as well as Madeira. He might mention that the present paper was the last of a series of four that had been read before the Society dealing with the African possessions of the Allies.

The paper read was—

PORTUGAL AS A COLONIAL POWER.

By GEORGE YOUNG, M.V.O.,
Ex-Secretary of Legation, Lisbon.

I have been asked how it is that, in addressing the Royal Society of Arts on a country so full of artistic interest as Portugal, I have chosen "Colonial Power" as a subject. But I need scarcely remind any one here that this is the Royal Society of Arts, Manufactures and Commerce, and this paper is the fourth of a series organised by the Colonial Section.

It would, no doubt, have been easier to interest you in other aspects of this most interesting people, but one is sure, to-day, of a sympathetic hearing from a British audience on any subject connected with our most ancient ally.

There is still, however, the difficulty that Portugal, though at our very doors, is as little known to most of us as the Pole. Indeed, I remember Sir Clements Markham saying, when I last met him at Lisbon, where he used to winter, that he had begun by exploring the Pole and had ended by discovering Portugal. Yet we have no excuse for this ignorance, for Portugal has been a pleasure resort since the Romans, having a perfect climate, picturesque scenery, and pleasant people. Moreover, it has been our ally for over five hundred years, the only two interruptions being when it lost its independence to Spain and to France. Here is a description of our relationship with Portugal from the "British Policy of 1347"—a sort of primitive commercial report:—

"Portugallers with us have troth in hand,
Whose marchandie cometh much into England.
They are our friends with their commodities,
And we english passen into their countries."

And if before the war we did no longer "passen into their countries," it was purely our own fault, though we must make an honourable

exception of our chairman, Sir Owen Philipps, whose Royal Mail steamers make the journey to Portugal a pleasure in itself.

If we have some idea of what Portugal is as a country and as a people, we shall find it easy to understand the past, present and future of Portugal as a colonial power, because an empire is only a sort of extra-territorial expression of the characteristics of the imperial people. We are proud of the British Empire, because we believe it to be an expression of much of what is best in our national character; and the Portuguese Empire reflects much of what is most characteristic in their race. Therefore when we realise what a large part in European progress this minor but very marked people has played, we shall also recognise that the colonial power of Portugal may, in this present crisis of civilisation, become a far more important factor than we might have supposed.

Let me, then, try to answer, in three-quarters of an hour, the three following questions:—How was the Portuguese colonial power constituted; in what does it consist; and what contribution can it make to the world which we hope to reconstruct from this waste of war?

The question how Portugal comes to be a Colonial Power has two answers. One would only require a reference to the map; the other, a review of European history. Neither being possible here, it must suffice to say that when Islamic intolerance finally blocked the direct routes to the East by Asia Minor or the Mediterranean, trade sought other indirect routes southward, along Africa, or westward across the Atlantic. For this leap in the dark geographical position made Portugal the best jumping-off place, and historical conditions made Portugal first ready to jump.

Portugal, then, by one of the curious contrarieties of history, owed its world empire to its worst enemy; for the whole history of Portugal is one long crusade against Islam. Portugal's first crusade was when the Christian refugees came down out of the Galician mountains to drive the Moor from Portus Calis, now Oporto. It was another crusade that, with English help, recovered Lisbon. Again, another in which Portuguese independence perished with the flower of Portuguese chivalry in Morocco. As late as 1717 Portugal undertook a crusade by itself, and it was not until 1843 that it signed its commercial capitulations with the Turk. Therefore the early empire-builders of Portugal were crusaders in the first place and only conquistadors or colonisers in the second. In every age we find the Portuguese pride of empire doing penitence whenever Portugal felt that it had offended against the crusading spirit.

The imperial poet of Portugal, Camoens, in his long panegyric of empire, the "Lusiad," finds place for such a protest against imperialism as the following:—

O Pride of Empire! O vain covetise
Of that vain glory that we men call Fame:
O false ideal, that finds its verities
In that vulgarity we "Honour" name.
What punishment and what just penalties
Thou dost inflict on those thou dost inflame:
What deaths and what disasters, what heart-breakings,
What hardships in thy cruel undertakings.

Now to what new disaster dost consign
This my dear native country—this my nation?
What dangers and what deaths dost thou design
Under some high and mighty appellation?
What profits from dominion or from mine
Dost thou propose for our remuneration?
What promises of Fame? What place in story?
What triumphs—what Te Deums—and what glory?

And if we come down to our own day, we find the prophet of the Republican Revolution, the poet Guerro Junqueiro, imperialist as he was, lamenting the loss of Portugal's ideals in this jeremiad:—

"I spanned the World about, new worlds among,
But not the more to worship and be wise.
A cruel greed hurried my feet along,
The pride of conquest made my sword-arm strong,
And lit the light of madness in my eyes.
I shall not wash the blood I then did spill
With tears of twice ten thousand centuries.
O Cross of Golgotha, new made in steel,
Sword of my paladins and cross of death:
Cross on which Christ bowed down for human weal—
Merciless, mighty, cutting through life a swath
To build up empires, bring the East in sway.
God breathed on them and lo! the empires fade;
But thee he planted, O thou blood-red blade,
In my wolf soul for ever and for aye."

Now, we English pride ourselves on our power of self-criticism, especially in imperial matters; but I know of no British imperialist poet in any age who reveals a higher recognition of the responsibilities of empire than these poets of Portugal. I have quoted them here to show that, in so far as empire is trusteeship, the spirit of Portugal is not unworthy of colonial power.

It was not until the maritime factor in exploration became dominant over the military that the age of chivalry began to merge into

the age of discovery, and crusading into colonising. And for the age of discovery Portugal was as well-equipped. For the mixed coastal population of Portugal, with strains of Carthaginian Greek, Norse, English and Dutch stock, supplied suitable captains and crews for the carrying out of the imperialist policy of an Anglo-Portuguese dynasty that originated, at the opportune moment, from the marriage of John of Aviz with Philippa, daughter of John of Gaunt. John of Aviz owed his throne to the English alliance, to antagonism to Spain, and to popular support. His dynasty having no basis either in legitimacy or in landownership, he had to raise public revenues for himself without arousing popular resentment. His position was like that of a squire who has succeeded to a big place and position without the property to keep it up, and so has to take to business. John's new business was that of foreign enterprise and empire, which provided new and easily taxable values. His sons carried it on between them, Prince Henry the Navigator taking over the technical side and founding Portuguese colonial power by formulating the science of navigation. This very English type of scientific nobleman, working in his remote laboratory on Cape Sagres, contributed to the age of discovery its first essentials—a ship that could sail the high seas without being swamped, and the courage, the capital, and the co-ordinated effort that then, as now, constitute the art of empire-building. He was no swashbuckling sea-rover—indeed, he was much more like that friend of our youth—

> . . . The old lady of Portugal,
> Whose ideas were excessively nautical,
> Who climbed up a tree
> To examine the sea,
> But thought she would never leave Portugal.

But what he did was to open up to the energies of the western world, pent up between the Ottoman Empire and the Western Ocean, the two lines—one upon the African coast and the other across the Atlantic—upon which the West might again get in touch with the East. By this he not only reopened the Old World, but revealed the New, for Columbus was merely carrying out his conception like any other of the sea-captains he inspired. Portugal indeed lost the crowning prize—the discovery of America—by the accident that the Portuguese King, to whom Columbus applied, had abandoned Prince Henry's line of advance south about round the Cape of Good Hope and overseas across the Atlantic, for futile exploration north about round the North Cape and overland across Africa. So he only referred Columbus to an expert commission, who, of course, took up his idea and turned down the author. Equally naturally, the captain they sent out soon lost courage and came back, while Columbus carried out Prince Henry's idea for Portugal's rival—Spain. In the same way Portugal lost to Spain the services of the Portuguese Magalhaens, and the honour of first circumnavigating the globe.

If, however, the Portuguese owed their colonial power partly to their ancient antagonists the Turks, and partly to their ancient allies the English, they developed that power very much on their own lines. Their proceedings, both in gaining and in losing this power, are very instructive to us; for in this, as in many other of the great political movements, Portugal has been a pioneer to Europe.

How was it, then, that the Portuguese, who had so good a start in the race for Empire, have now dropped so far behind? Why did empire-building so exhaust them that they could no longer hold their own walls against Alva and Spanish militarism, whereas it gave us strength and skill to hold the seas against the Armada? The answer is that the Portuguese were by race crusaders and missionaries; we colonisers and merchants. They were proselytising for the Church; we prospecting for chartered companies. This difference was partly due to temperament, partly to the times; for the reign of the middle class, under which our Empire was built, had not begun. The consequence was that when the wealth of the Old World and the New began to pour into Lisbon, neither the Court, where the English element had become insignificant, nor the Church, nor the upper class, could do any good with it. Nor would they let anyone else put it to profitable use. When the Jews began to control it, and make Lisbon what London afterwards became under similar conditions, the Church ruined Portugal by persecuting them. Just as, later, when the Jesuits began to control the commerce of the empire, their system was broken up by the Crown and Pombal. In a word the Portuguese Empire at first had no business basis. We and others profited by Portugal's crusades against the obscurantism of Islam that barred us from the East, and the obscurity of ignorance that blinded us to the West.

Coming next to the question as to what constitutes the colonial power of Portugal, we find that it was from the first divided into three distinct and very different developments. These

correspond to their colonising enterprises in the three continents, Asia, America, and Africa, each of which had a different character and a different course. The Asiatic empire was, broadly speaking, aristocratic; the American, democratic; the African, bureaucratic. Portugal in Asia has died of disease and decay; Portugal in America has grown to giant size, but has for a century gone off on its own; Portugal in Africa is still in an infancy as full of promise as of problems. Therefore, in a moral sense, Portuguese colonial power to-day consists of the historical relics of Portugal in Asia, the cultural relationship with Portugal in South America, and the material resources of Portugal in Africa. Strictly speaking, Portuguese colonial power comprises, in Africa, the great undeveloped possibilities of Angola and Mozambique and the highly-developed cocoa islands; in Asia, Goa and some other settlements that are dead, Macao that is dormant, and the island of Timor that is undeveloped. The rest are insignificant. Madeira and the Azores are practically Portugal.

Of the three developments in Asia, America, and Africa, by far the most brilliant was the brief blaze of glory in which the Portuguese Empire in India burnt itself out. "Golden Goa" was a characteristic product of the brief and brilliant "Golden Age" of Portugal. In its best aspects it was also an anticipation of our Indian Empire. The prototypes of our great proconsuls were Portuguese noblemen like Albuquerque and Noronha. Types of chivalrous soldiers like Outram and Gordon are as easy to parallel in the history of Portuguese India; for in the age of chivalry Portugal was among the first of all European peoples. We may recall, in passing, that the ladies of the Court of Edward III. asked for twelve Portuguese knights to teach the English manners. And as the common soldier replaced in importance the cavalier, Portuguese infantry were again among the first. Let me call in evidence the "Iron Duke" himself, no admirer of foreigners, who towards the end of the Peninsular War brigaded Portuguese infantry with the famous Light Division as their equals. For such leaders and such troops the conquest of India seemed a certainty. The first fruits of that conquest had, indeed, in a few years made Lisbon the most splendid Court in Europe, and likely to become the capital of the civilised world. But the whole splendid structure was rotten, and its gilded cupolas and soaring pinnacles had no foundation. It was predatory and parasitic, with no real life of its own; it became mere priest-ridden profiteering, corrupting everything with which it came in contact. From a crusade for the national ideals of Portugal, it became a conspiracy against those ideals. Like an evil incubus it drained the vigour of Portugal, and in return demoralised it with its gold and jewels. And so to-day the Portuguese power in India survives only in a few enclaves on the map of British India, with names known only to history, and a few Eurasians in the middle class with names that once were known throughout Christendom.

In this last feature we find a suggestion of another reason why the Portuguese Indian Empire failed. One was that it became rotten through having only a parasitic vitality; the other was that it allowed the native stock on which it was grafted to sap the imported culture. The Portuguese Indian Empire, like ours, was based on the rule of a caste apart, and this required respect for the colour line. But the policy of the colour line is as repugnant to Portuguese philanthropy, to their instinctive humanity, as is slavery to ours. In other words, their humanity is personal; ours predial. They look on a native as an inferior fellow-man; we as a superior foreign mammal. Either point of view has both its advantages and its disadvantages for both the dominant white and the dominated coloured race; but the Portuguese policy of intermarriage is as clearly incompatible with the principle of caste government as ours is unconformable to the principle of co-operative government. The Portuguese lost India because they were too racially democratic to be rigidly aristocratic. If we ever lose India, it will be because we are too rigidly aristocratic to admit of any real democracy.

In the Portuguese Empire in America, now the United States of Brazil, we have a Colonial Power that was in the opposite extreme. Both its genesis and exodus, so to say, were democratic—even more democratic than our colonial system in North America. The result of this absolute democracy of the Brazils was, in the first place, no war of extermination with the native Indians; in the second place, no external war of independence between the American democracy and the European aristocracy; and in the third place, no internal civil war between the aristocracy of the colonies and their democracy. The crusading element in this Portuguese enterprise took a missionary and not a militarist form, and was represented by the Jesuit missions. Whatever we may think of the work

of the Society in South Europe, there can be no two opinions as to their work for humanity in South America. Thanks to them, the whole imported culture has been so grafted on the native stock that the South American of the future will not be merely a new Portuguese, a revised edition of a North European, but a Eur-American, with potentialities as vast as those of his territories. The world's future in music, art, and literature may well lie with the children of Portuguese culture in the Brazils.

The vitality of this Portuguese colony, both as a colony and as Portuguese, contrasts curiously in both respects with that of the Indian colony. The Indian colonies, when Spain conquered Portugal, became Spanish automatically. But when the Brazils were sacrificed by Spain to the Dutch to save Spanish possessions, the colonists resisted successfully all attempts to alienate them from Portugal, and returned to their allegiance at the first opportunity. Moreover, it was the tribute from Brazil that enabled the Braganzas, after the restoration, to throw off the Spanish rule, and also, unfortunately, to throw over the Portuguese reformers and govern for two centuries as absolute monarchs. The result of this last was that the tie became merely dynastic, and when the Portuguese monarchy fell under the strain of the Napoleonic wars, Brazil became automatically independent. The United States of Brazil, like those of North America, owe their separation to a misuse by the mother-people of the monarchical principle.

In Portuguese politics Brazil has played an important part. As when Pedro, Emperor of Brazil, came over to put an end to the reactionary despotism of his brother Miguel, or when Brazil, after becoming a republic, contributed to the present renascence in Portugal by supporting the Republican Revolution.

In Portuguese economics the contribution of Brazil has been very considerable, owing to the fact that in the Portuguese economic balance-sheet the remittances from Brazilian emigrants count for as much as one-half of the total incomings. Portugal itself produces little, purchasing much of its food abroad, and pays heavy interest on a disproportionate debt, two-thirds of the proceeds of which have been wasted. To pay for all this, Portugal must export something, and has nothing but the produce of its African colonies and the population of its own countryside. This enforced emigration has been particularly ruinous to Portugal, and the Republican reformers are pledged to remedy it. It was, indeed, one of the causes of the Revolution, and Guerro Junqueiro, the revolutionary poet, finds in it a subject for the *sæva indignatio* that made his poems a political power. It must be remedied before there can be any return of prosperity to Portugal itself and any real reconstruction of the African Empire.

There remains, then, to Portugal this African Empire, the vast tracts of territory that were Portugal's founders' shares in the European flotation of Africa. Until quite lately these colonies were only a financial and political embarrassment, and under the monarchy the proposal to trade them off against the burden of debt found favour. The Republican reformers rejected this as treason, and their view has since found practical justification. For there has been a considerable and increasing contribution to the economic balance-sheet from the control retained by Lisbon of the produce of these colonies, notably the cocoa islands. But the Republican reformers, in their task of making the Portuguese Empire pay, have had formidable difficulties to contend with. The first dilemma was that between colonial secession if the mercantile system and central administration from Lisbon were retained, and loss of all profits if it were abandoned. This has been dealt with by a generous grant of self-government, while control of colonial produce is retained by customs regulations.

Then came the difficulty that the colonies could only be exploited by native labour, and this caused trouble with the natives and with foreign philanthropists. This has been met by a regulation of native rights and of conditions of contract labour that works well and has been generally recognised as satisfactory.

Thirdly, the worst dilemma was that Portugal had neither the money-power nor the man-power to develop the vast resources of these regions quickly enough to satisfy the demand for their raw materials. Before the war it looked as though such development would, with all outward observance of Portugal's eminent domain, be taken over by other Powers. This situation has now been simplified by the participation of Portugal in the war. Whatever the future of the Portuguese colonial power in Africa may be, it will only now be fulfilled with the full approval of the Portuguese people.

Finally, we have to find an answer to the question what contribution can Portuguese colonial power make for good or ill to our reconstruction of civilisation.

There seem to me to be two possible principles of peacemaking. One, restoration as far as

possible of the *status quo ante bellum;* the other, reconstruction. We should all prefer the latter, and in respect at least of the future status of Africa we shall be in a position to impose it. Nor shall we, to judge from the latest Prussian pronouncements, encounter much opposition from them if we use our power in the general international interest, and not exclusively in our own imperial interest.

But let us suppose that conditions elsewhere impose on the Allies an African settlement that is rather a restoration than a reconstruction. In that event the contribution of Portuguese colonial power will not be for the good either of Portugal or of Europe. Portugal will indeed, by participation in the war, have improved its *ante-bellum* position so far as concerns protection of its possessions by the Allies, but this protection can only operate in so far as war conditions continue or can be recommenced; for the peace basis of Portugal's possessions was the counterpoise between British and German economic and political interest in them—a counterpoise in which the conservative interest of Great Britain counter-balanced the covetous intentions of Germany. Just before the war this balance had been upset economically and politically, both as regards the colonies themselves and their controlling centre in Lisbon. The deadlock between the rival interests of the Great Powers had been replaced by a delimitation of economic interest in the African territories. It looked as though the Portuguese possessions might have to exchange the agreeable *rôle* of a *tertius gaudens* for that of a *tertium quid.* But more was involved than Portugal's immediate loss of economic control, and ultimate loss of political control, of these colonies. We have seen how important the profits from colonial produce are to the mother-country. Now, the natural market for this produce was, before the war, and will be after it, in Germany. The natural money centre for financing this production would be Lisbon. But Lisbon has neither the capital nor the credit even for financing the existing exploitations, still less for floating new enterprises. Consequently financing operations have passed to the only other parties interested, the German consumers, and are mainly in the hands of German firms in Lisbon. But these operations, being by far the most important financial business in Lisbon, have tended to carry with them not only considerable control over economic developments in the colonies, but also over the economic existence of the capital. And where there is economic control there is an essential element of political control. Before the war German business enterprise, both private and public, had made considerable progress towards supplanting British trade in its secular pre-eminence in Portugal. Courage, capital, and co-ordinated effort are the essentials of the art of empire-building, by whomsoever they are exercised.

If, therefore, the principle of the settlement in respect of Portugal and its possessions is restoration, and not reconstruction, we shall find this process resumed. In that case, Germany may—indeed, Germany must—continue the economic penetration of Portugal and its possessions to its inevitable conclusion in German political predominance over both the home country and the colonies. Recent events suggest that this process will be prosecuted by a restoration of the monarchy under a German prince and a reversionary interest in the colonies in return for relief from debt. We may recall that under the late monarchy there were serious proposals to sell some of the colonies, including Goa, to Germany, and that the Republicans are pro-British; the Royalists, with the exception of some "Manoelists," are pro-German. Should Portugal become a Germanophil Principality, and its possessions Germanic protectorates, the map shows us what this would mean to the prospects of peace for us English. To us, as Europeans, it would mean the permanent partition of Europe into two armed camps, and the permanent partition of Africa into two or more colonial cartels. The integral independence of Portugal is only one degree less vital to us than that of Belgium. The future of Africa is involved in that of the Portuguese colonies.

We should, no doubt, combat this course of events by political and economic action. By instituting a trade bank at Lisbon, by sending out trade commissioners, and by increasing transport facilities we could do much, and we have previous failures in such efforts to profit by. But in case of a settlement by restoration only, the contribution from Portuguese colonial power will be mainly to present us with some very difficult problems.

Now, therefore, let us take the other alternative —that of reconstruction on a more or less international basis. The European exploitation of Africa has always had both an imperial and an international character. Its main function, that of supplying Europe with raw material in return for capital and control, is essentially international. But as competition for such

control increased, first the administration and then the exploitation of Africa was partitioned into imperial protectorates and parcelled off into preserves of the Great Powers. Their Governments did not sufficiently represent the social entity and economic solidarity of Europe, and the international element of the European exploitation was not expressed in institutions, or where it was so expressed, as in the Congo Free State, it was allowed to lapse.

But one result of this war—if it is, as all sides say, a crusade for civilisation—will be a movement to reconstitute and reinforce the common interest of civilisation by various international institutions. In Europe the international interest will be expressed in some form of *confederate* authority, such as the League of Nations. In Africa, by some form of *federal* authority. This federal authority, while recognising the existing administrations and annexations, would co-ordinate and control them in the international interest of free trade for all nations and fair play for all natives. The colonial power of Great Britain, France, Portugal, and Germany must all contribute towards the establishment of a Colonial Power of Europe.

Such a reconstruction on an international instead of a national basis removes or relieves all difficulties—the difficulty of Portugal in developing its possessions without being deprived of them; our difficulty in defending Portugal and its possessions without raising a "war after war" or risking another "war to end war"; the German difficulty of getting enough colonial produce without having enough colonial power: the European difficulty in preserving peace and protecting the natives.

Can we on such conditions count on Portugal's readiness to make this contribution? In view of the fact that Portugal could scarcely meet the charges on its foreign debt if it renounced the revenues from colonial produce, it would be proper that a compensating relief from debt should be arranged by the new federal authority for Africa as an African national debt. And if in terms of territorial area the contribution of Portugal to the new federation would be rather more considerable, say, than ours, yet the benefits accruing would be correspondingly greater; for the security of investment that would result from the federal regulation of exploitation would enable Portugal to develop its colonies without mortgaging them to any other Power. For a policy of internationalism that would save Central Africa from German or any other imperialism, we can count on the contribution of the Portuguese Republic with confidence.

It is on this note of confidence that I would close this consideration of Portuguese colonial power by quoting from the poet-president of the Republic, Dr. Braga. After reviewing the services to humanity of the great world empires, he defines the contribution of Portugal thus:—

And with what arms shall Portugal engage,
So little as she is, in such great feats?
They count on her to take a leading part
Who know that in the Lusitanian heart
Love beats.

DISCUSSION.

Major E. H. M. Leggett, R.E., D.S.O., in opening the discussion, said some might have thought that a note of sadness ran through at any rate the first part of the paper, which seemed to be a kind of requiem of the past glories of a great imperial people, but the author went on to analyse the reasons for that, and at the conclusion of the paper he used the words: "I end upon a note of confidence." There was one point that the author had not developed, and that might be taken as having run through all the four papers which had been read before the Colonial Section of the Society on the African Possessions of the Allies, and that was the common ideal which actuated the four great Allied African Powers of to-day: the sense of trusteeship towards the native, the conviction that development to be sound, permanent, and profitable in the best sense to all concerned must be founded on a just policy towards the native, who must have as large a share in the profits of that development as the controlling European Powers. That was the point that differentiated the African policy of the Allies from that of Germany, whose policy in Africa was founded upon militarism and upon *quasi*-slavery. Germany looked upon the African native as a hewer of wood and drawer of water for the benefit of the controlling white Power. When the author came to his final suggestion of the reconstruction of Africa and discussed it on the lines of internationalisation, he could not help feeling that before such a reconstruction into which Germany could be admitted was possible, there must be an absolute end of the German policy towards the African races. But was Germany likely to adopt any change in her policy? Only last week the German Colonial Secretary stated that the aim of the Imperial German Government was to regain the colonial possessions of Germany and to develop them into a strong and economically productive whole, that there must be a just redistribution of the colonial possessions of all nations in Africa, and that the standard for that redistribution must be, from the point of view of power, the ratio of the physical strength of the States concerned. "Power"—not trusteeship. Power for the drawing of the economic products of Africa to the benefit of the European comity of nations? Not at all, but solely for Germany. If German

militarism was not defeated that country would extend its rule from the Zambesi to the Sahara, and the colonies of Portugal, Great Britain, Belgium and France would disappear. It must never be forgotten how radically the policy of Germany towards Africa, and towards its indigenous populations, differed from that of the Allied Powers towards the same.

MR. JOHN H. HARRIS thought that in the reconstruction of the African continent the main factor would be that of considering the reconstruction of our treatment of the native races. After all, the German colonies would be of very little use to Germany if they were restored, unless some means were found for providing those territories with the necessary population. In the part of Africa known before the war as German South-West Africa, the population was so sparse that there were actually three square miles to every native, and in Togoland the population had been reduced during the last thirty years from 2,500,000 to 1,500,000. The same problem confronted Portugal to a very considerable extent. The economic success of the cocoa islands was very pronounced, but that success was after all only maintained by a continuous importation of labour. In all colonial industries some means must be found for the provision of adequate supplies of labour, and it was remarkable how much could be done in that connection by very careful attention to the health and the general conditions of the labourers. The death-rate of the natives employed in the mines of the Rand had now been reduced to something like twelve per 1,000, which was a very great reduction from the heavy death-rate of former times. Some people were beginning to wonder whether the time had not arrived to associate the natives of Africa much more closely with the industries of the Continent. During the last fifty years there had been a very remarkable development amongst the natives themselves; in West Africa to-day there was a considerable number of natives of quite substantial means, some of them receiving salaries or incomes of from £500 to £1,000 a year. The fact that they were assuming important positions in Africa seemed to point to the necessity of providing them with some means of investment more ethical than a plurality of wives and more economically sound than a redundancy of cattle. Many people were now seriously considering those two points—whether in the reconstruction of Africa a better distribution of the native population could be secured, and a closer alliance between African labour and African industries. In Portuguese territories probably as good opportunities would be found for carrying out those ideas as in the colonies of other Powers, particularly in view of the fact, to which the author had drawn attention, that there was less of the colour prejudice in Portuguese colonies than was to be found in the colonies of any other Continental Power.

SIR FREDERIC S. P. LELY, K.C.I.E., C.S.I., in proposing a vote of thanks to the author, said the subject of Portugal was an extremely interesting one. He had been greatly struck by the comparison between the vitality of Brazil on the one hand, and what he was afraid was only too justly called the degeneration of the Portuguese national character and position in India. Personally he had had Portuguese for his neighbours in India, and he had very pleasant recollections of his intercourse with them, and was not prepared to admit that there was no future before them in that country. There was no doubt that India had owed something to the Portuguese in the past. At the present moment the only benefit he could remember that the Portuguese had conferred upon India was the improvement of the mango, the Portuguese being very expert gardeners. He thought their two main defects in India were that their civil government was too much confused with religious propaganda, and that they were too completely severed from their own homeland. He hoped that, in the rearrangement of the world that would take place after the war, Portugal would play a great part in happy alliance with this country. One very suggestive point had already been alluded to, namely, the extraordinarily different attitude adopted in Brazil towards the coloured races from that adopted, for instance, by the United States of America. Lord Bryce had stated that in Brazil there was absolutely no such thing as colour prejudice, and that the races mixed, even in marriage, in the most unrestricted way.

MR. BYRON BRENAN, C.M.G., seconded the motion, which was carried unanimously.

The meeting then terminated.

CASTOR-OIL PLANT.

Of late there has been considerable inquiry as to the cultivation of oil-yielding plants, including the castor oil. There is ample evidence that this plant will thrive almost anywhere on the coast lands of Queensland. In and around Brisbane, the *Queensland Agricultural Journal* states, it may be seen growing and bearing heavy crops of seed in all sorts of out-of-the-way places—on the river banks, in quarries, on unoccupied allotments, etc.; and this applies as well to other coastal localities in Central and North Queensland. No attention has, however, been given to it with a view to turning a plant which is looked upon almost as a noxious weed to profitable account. Most people, especially children, know to their sorrow that castor oil is a most valuable medicine; but not many are aware of the large quantities which are used for lubricating machinery and for illuminating purposes. In India it is used on all the railways in the signal and carriage lamps, owing to the brilliancy and safety of the light. It burns very slowly, and thus is more economical than other oils.

The plant is exceedingly hardy and will stand

a wide range of climate. The seeds have extraordinary vitality. Oil seeds, as a rule, quickly lose their germinating power; but the castor seed seems to be an exception. Seeds known to have been kept for fifteen years in a bottle have been sown in Queensland, and have produced healthy plants. In a tropical or even subtropical climate the plant becomes a perennial tree instead of an annual, attaining a height of from 20 to 30 ft. The best soil for castor is much the same as that required for the cotton plant—a rich, well-drained, sandy loam. It will not thrive on heavy, wet soils. As the roots penetrate very deeply, the land must be deeply ploughed and well worked. The seed is planted in rows 6 to 8 ft. apart each way, three or four seeds being planted in a hole Before planting they should be softened by having hot water poured over them, and then being left to soak for twenty-four hours. In ten days after sowing the seeds will germinate, and when the plants are 8 or 10 in. high the three weakest must be taken up where four seeds have been put in. They grow very rapidly, and begin to bear in four months. Like the coffee and cotton plants, the castor plant would grow to an inconvenient height if left to itself. It should, therefore, be kept low by pinching back the main stem. This will have the further effect of causing the plant to throw out many more fruit spikes than it otherwise would do. When the tree gets old, the usual scale insect (the *Coccus*) attacks the bark. They have to b dealt with, as in the case of citrus and other fruit trees, by spraying with kerosene emulsion.

When the capsules turn brown it is time to begin the harvest. This is done by cutting off the spikes and removing them as soon as possible to the barn. The work of harvesting must be done rapidly, for if the seeds are allowed to ripen on the tree the pods burst open and the liberated seeds fly in all directions. This "popping" of the capsules makes the matter of freeing the seeds a very simple one. All that has to be done is to prepare a drying-ground either in a shed or in the open. The ground should either be boarded or swept quite clean. When the spikes are brought in they should be spread out on the drying-ground to the depth of from 6 in. to 1 ft., according to the heat of the weather. Should rain occur when out-of-door drying is being carried on, draw the spikes into heaps and cover with a tarpaulin. Turn the spikes over frequently to let all get the benefit of the sun. The capsules will soon begin to burst, and in four or five days they will have shed all their seed. All that remains to be done is to sift or winnow out the husks. When drying in the open, it is well to surround the drying spikes with a low rampart of galvanised iron or bagging, for the reason that many seeds fly out very violently, and without some such precaution they would be lost.

The return from an acre is about 20 bushels, a bushel of seed weighing 46 lb.

In India the seed is crushed between rollers, placed in hempen cloths, and pressed, and then the oil is heated with water in a tin boiler until the water boils. This separates the mucilage and albumen, the product being finally strained through flannel.

Cheap wooden rollers would serve the purpose. and these could be driven by a horse gear.—*The Colonial Journal.*

RAILWAY SURVEYING IN CHINA.

The following statement regarding railway surveying in China, written by an expert, has been sent to his Government by the United States Consul-General at Shanghai :—

At the outset it must be realised that, with the exception of the coast-line and the great navigable rivers, there are no accurate maps. Consequently, when it is proposed to build a railway between two definite places it is frequently the case that the intermediate country is as unknown as if it were in the remotest parts of Central Africa. The two main considerations in designing a railway are straightness and levelness. The latter is in many ways more important than the former, since a steep road requires more powerful locomotives and is therefore more expensive to run.

The work of surveying usually proceeds in several stages. First of all there is a reconnaissance. An experienced engineer walks or rides over the country between the two places and explores every possible route. By noticing the times required to traverse short lengths (say. five miles or so) and the magnetic bearing of such short lengths, he obtains a rough idea of the distance, and by means of a barometer he observes the heights of the mountain passes or ridges over which the line may pass.

The responsibilities of this part of the work are very serious, because the engineer must usually decide on the abandonment of certain routes, and in many cases it is difficult, with the information at his disposal, for him to feel sure that his choice of route or routes is the wisest. He must possess great powers of judgment and also experience in similar work to know .f the economic and engineering peculiarities of a certain route warrant its further consideration.

The work is also arduous, since he must walk or ride twenty or more miles per day, personally examine every possible position, and be prepared to camp almost anywhe e.

The next stage is the preliminary survey, and is a much more elaborate process. The reconnaissance having shown which routes need to be more carefully investigated, a regular survey is made along the lines laid down on the small-scale, rough maps prepared by the exploring engineer. This is generally done by one or more

parties, consisting of a chief of party, one or more assistant engineers, several surveyors (generally Chinese students), and numerous survey coolies.

The chief of the party goes in front and makes a more detailed study along ten to thirty miles of the route indicated by the reconnaissance, and returns personally or sends word to the chief assistant as to details to be observed. He himself, or one of his assistants, then proceeds to fix pegs from 100 to 1,000 yards apart, between which lines can be measured with a chain. By means of a theodolite or transit the direction of these lines is observed.

The domestic arrangements of a survey party are very similar to those of the exploring engineer, except that the survey advances with much less speed (rarely more than five miles a day), so that it is not necessary to move camp every day. On the other hand, a difficulty occurs from the very size of the party. There may be, including carrying coolies, more than one hundred persons, and it is not always easy to secure accommodation for so many, especially in the less densely populated parts of the country. On account of the great expense and the desirability of speed, the working hours are from sunrise to sunset.

Trees and undergrowth must be cut away along the line so as to allow it to be chained, and measurements taken. Sometimes it happens that the line passes along the steeply sloping side of a hill, and then, on account of a projecting spur, rises suddenly up and falls again, so that a small element of danger is present.

When this survey has been completed, the final position of the railway may be chosen and drawn on the plan. Estimates as to the cost of filling in and cutting out, building bridges, etc., can be made, and it will then usually be decided whether to proceed further or not. If it is decided to proceed, the next step is to "locate" the line, which means to peg out the exact centre line. This is still more tedious than the preliminary survey, since the line must be followed, no matter where it goes.

SHANTUNG WOOL.

The following synopsis of a report on Shantung wool, prepared by the Imperial Japanese Military Administration of Tsingtau, has been sent to his Government by the United States Consul at Tsingtau :—

Wool in China is produced chiefly in Mongolia and North China. While the quality of Chinese wool may not equal the Australian product, the greatly augmented demand at present has caused an increased export, especially to Japan. Shantung Province is one of the principal wool-producing regions of North China. Shantung wool is commonly classified as "spring" and "autumn" wool, depending upon the time of shearing, and into "fleece" and "raked" (literal translation of Japanese terms) wool, according to whether it is sheared or raked from the sheep. There is produced and exported, also, a relatively small amount of goat's hair, in quality superior to sheep's wool—that is, raked from the goat's back in the spring.

Owing to the method of caring for the wool and the character of the wool itself, Chinese wool is used only for coarse articles like carpets and blankets. Probably 1,300,000 lb. of wool are produced annually in Shantung, of which one-fifth is consumed locally and four-fifths exported through Tientsin and Tsingtau. In addition to this amount, outside wool to the extent of about 250,000 lb. is brought into the province for sale. The wool is collected in the interior through brokerage houses, who charge 3 per cent. commission. Sometimes purchases are made direct from producers, either when the wool is displayed for sale or by forward contract.

THE SWISS CHEMICAL INDUSTRY.

According to the annual report of the Basle Chamber of Commerce, the Swiss dye industry views with great concern the rise of a dye-manufacturing industry in other countries, particularly in England and America. It was thought at first that the development of such an industry in other countries would be seriously handicapped by lack of the cumulative experience and inherited skill of many years, but, owing to the fact that Swiss chemists have in many cases offered their services, this industry has already made great strides in the countries named. The report states that in America especially dye factories have sprung up like mushrooms, and there is already danger of over-production and consequent disaster. Reference is made to British Dyes, Ltd., in England, and also to the French company. The prospect of establishing a dye industry in Italy is not considered bright.

In regard to acids, the report goes on to say that the greater part of the production of hydrochloric, sulphuric, and nitric acids is required for the manufacture of munitions in Switzerland, so that there is a great scarcity of these acids for other purposes. A new sulphuric acid factory is, however, being erected in Schweizerhalle. Also the new Swiss soda factory at Zurzach was able to commence manufacture in August, 1916, although the output is at present very small.

The supply of raw materials from England and America is gradually becoming less, and the difficulties of the Swiss chemical industry are correspondingly greater. But the greatest difficulty of all is the prospect of a coal famine, especially in view of the fact that the supplies of substitutes such as wood and peat are not very plentiful. The manufacture of artificial indigo is now very seriously handicapped in Switzerland owing to the lack of raw material.

ENGINEERING NOTES.

An American Submarine Boat Yard.—The *Engineering News Record* gives a detailed account of the submarine shipyard in New Jersey, U.S.A. The yard occupies about 125 acres at the southerly end of the new Port of Newark Terminal. This terminal, belonging to the Submarine Boat Corporation, has been under construction for a few years past. It comprised, when taken over for shipbuilding last August, a flat sand fill some 5 ft. above high water in Newark Bay, with a parallel frontage of about 2,700 ft. on the bay, where the depth of water at present is 12 ft., and extending back about 1,800 ft., with a channel on one side. The site is about four miles from the City Hall of Newark. The whole area has city sewer and water connections. A bulkhead dock-wall exists alongside the property. In this yard will be built, according to present plans, one hundred and fifty 5,000-ton boats. The entire plant is to get its power from local electric power companies, between 9,000 and 13,000 h.p. being the estimated power required. The compressor houses and transformer for the shipways will be located in small houses between every fourth set of ways, there being seven such houses to the yard.

Improving Cast-iron with Uranium.—By alloying uranium with cast-iron or semi-steel, the strength and toughness of the metal is increased, as well as the fluidity, according to a patent (U.S.) says the *Iron Age*. The quality of the iron for machinery is claimed to be enhanced and the resistance to wear increased. The new alloy is made by adding uranium to the molten iron as uranium metal, or ferro-uranium, so that the finished product will contain from 0·05 per cent. to 0·10 per cent. of uranium. The addition of this element is said to deoxidise and denitrogenise the metal, increasing the tensile strength and producing a fine grained product.

Water-power in Tasmania.—"When the electrolytic zinc works at Risden," says Mr. J. H. Butters, the Chief Engineer and Manager of the Hydro-Electric Department of Tasmania, "are ready to take their first instalment of electrical energy—4,000 h.p.—which will be in a few months, the Tasmanian hydro-electric scheme will be loaded up to its full present capacity of 10,000 h.p. We are preparing to increase the capacity to 30,000 h.p., but just at present it is impossible to secure the material for the steel pipe-line. That the Great Lake can give us the water for 30,000 h.p. is a matter that admits of no doubt. All my estimates have been based on a conservation of enough water in the lake to give 35,000 h.p., but for a long time past enough water has been flowing out of the lake to give us twice that, or 70,000 h.p., if we had the machinery to develop it. The surveys relating to the proposal to harness the King River to supply the 20,000 h.p., which the Mount Lyell Company desires to use in the work of treating the complex zinciferous ores of the Read-Rosebery group have been completed. The designs for the work are now being drawn up, and will be submitted to the State Parliament during the coming session. If Parliament approves of them, we shall be able to go straight ahead with this work."

Conversion of Sawdust into Gas.—With the object of effecting a further reduction in the transit and use of anthracite coal for gas-making for gas engines, Mr. W. T. Crampton, M.Inst.M.E., suggests, in the *Daily Telegraph*, the value of suction gas. For the conversion of sawdust into gas, the plant is slightly larger than for coal, and with the use of a tar extractor, the principle is the same. The possibility of the use of this waste is not generally known, and consequently the volume of sawdust destroyed and wasted is serious.

Steaming Capacity of Locomotive Boilers.—A writer in the columns of an American engineering contemporary, says the *Railway Gazette*, lays down some rules the observance of which would, he states, ensure superior steaming qualities in locomotive boilers. Every engine should have as large a nozzle as it is possible to use, and thus enable the engine to make steam freely. If an engine is failing for steam, the nozzle should not be reduced until full investigation has been made, in order to determine whether or not the engine has any other defects which might in any way contribute to the failure. It is necessary that all joints around the front end should be kept absolutely airtight, and that the area of opening in the front end netting be as large as possible. The air opening in the ashpan should not be less than 14 per cent. of the grate area and 100 per cent. of the tube area. Insufficient air opening will probably make it necessary to operate the engine with a reduced nozzle opening. A reduction of from $\frac{1}{8}$ to $\frac{1}{4}$ in. in the size of the nozzle might easily cause a waste of from 2,000 to 4,000 lb. of coal per trip over the average division. Leaky steam-pipes or nozzle-stand joints will cause a waste of 2,000 to 4,000 lb. of coal per trip. Steam pipes should be tested every time an engine is held in for repairs as long as two days or more.

The First Large Concrete Ship.—Last August the San Francisco Shipbuilding Company began the construction, at Redwood City, California, of the ways for the building of a reinforced concrete ship of 7,900 tons displacement, with a deadweight carrying capacity of 5,000 tons. The laying down of the ship was started in September, and the vessel was to be ready for launching on March 1st. Had it not been for changes of plans and the employment of a new naval architect, the vessel would probably have been ready for the water on February 1st. The ship is 336 ft. long over all, 45 ft. in beam, and 31 ft. deep to the upper deck. The draught loaded will be 24 ft. The ship will be equipped with Scotch marine boilers and 1,750 h.p. triple-expansion engines. The speed, according to the *Engineering News-*

Record, will be ten knots. The company now has under way designs for four ships of 7,500 tons dead-weight carrying capacity.

Generating Steam with Electrical Energy.—The Swiss Society of Steam Boiler Owners has carried out tests on the commercial possibilities of generating steam with electricity derived from water-power. A small boiler was used with thirty-eight steel tubes, in thirty-four of which were placed heating coils. An evaporation of 2½ lb. of water per square foot of heating surface was obtained, and the efficiency was 90 to 91 per cent. To compete with coal in Switzerland, at 44*s*. per ton, the cost of energy would have to be not more than 0·08*d*. per unit. Owing to the scarcity of coal, which now costs over £3 a ton, and is likely to reach £4, the working of the Swiss railways is costly and difficult, and the feasibility of using electric heating on steam locomotives is being seriously considered. While the complete electrification of the railways cannot be accomplished at present, the supply of electricity to the locomotives would present less difficulty, and the cost of energy from water-power would be only 0·15*d*. per unit, which would be comparable with the cost of coal. In view of the possibility that the supply of coal from Germany may be completely stopped, the subject is of some importance to the railways, which would have no alternative in such an emergency.

A Long Continuous Girder.—In America, where they often do large things, they have just completed the Sciotoville Bridge, over the Ohio River, which is the largest continuous work of the kind on record, being 775 ft. span. The subject of this method of construction was discussed by the Society of Engineers, as recorded in our notes on May 11th last. The continuous beam is not usual in bridge work for road or railway purposes, for the reason that there is an amount of uncertainty about the position of the point of contrary flexure, as it is called, owing to the live load, as against the dead load, which only has a fixture of one-fourth of the distance from the piers. However, the bridges on the Madras Railway, on the comparatively moderate spans of double 70 feet, were fixed many years ago on that principle, and several remain so still, though some of them were superseded by greater flood openings, due to other causes than to the continuous theory. The uncertainty about the position of contrary flexure was solved by the approximate and safe provision of sufficient metal, and the object of the arrangement was to enable the girders to be rolled over two or more piers from the abutments; hence the avoidance of the expense, and risk from flood, of staging.

OBITUARY.

KENNETH J. CAMERON.—Information has been received of the death from pneumonia of Mr. Kenneth J. Cameron, which took place on November 18th at Zomba. He belonged to the Nyasaland Volunteer Reserve, and was attached to the South African Engineers, who were engaged in keeping up road communication between Railhead and Lake Nyasa.

Mr. Cameron was born at Lochaber in 1862. He worked for some years at the Royal Botanic Gardens, Edinburgh, and at the same time studied at the School of Art, where he obtained his Art Teacher's certificate. In 1890 he accepted a five-year engagement under the African Lakes Company, Ltd., and at the termination of this he started as a coffee-planter on his own account. He made a careful study of various insect pests, and he also experimented in growing cotton, tobacco and indigo.

He was elected a member of the Royal Society of Arts in 1901.

VICE-ADMIRAL WILLIAM USBORNE MOORE.—The death is reported at Southsea of Vice-Admiral William Usborne Moore, who had been a member of the Royal Society of Arts since 1891. Born in 1849, he entered the "Britannia" in 1862; in the following year he joined H.M.S. "Revenge," and subsequently served as assistant surveyor on H.M. ships "Newport" and "Sheerwater." He was then selected to take charge of a survey of the Fiji Islands, which occupied him for five years. From 1882 to 1885 he commanded the "Dart" on the Australian station, and acted as Deputy Commissioner of the Western Pacific. In 1885 he was promoted commander and proceeded to the China station. He obtained his captaincy in 1892, and three years later was given the home survey on board H.M.S. "Research." For nearly twenty-five years he was in charge of surveys at home and abroad, the triangulation along the coast of China for many hundreds of miles being one of his most notable achievements.

NOTES ON BOOKS.

A POCKET HANDBOOK OF MINERALS. By G. Montague. Second Edition. New York: John Wiley & Sons, Inc.; London: Chapman & Hall, Ltd. 11*s*. 6*d*. net.

A pocket book or field book comprising somewhat over three hundred pages, and conveniently bound in limp covers, is here presented to the reader.

The preface is, to a considerable extent, a laudation of the book, and, *inter alia*, we are told that "nothing is herein included which may not be needed in the pursuit of the end for which the book was prepared—*i.e.* the determination of minerals." Turning to mercury—which, as a mineral, occurs in minute fluid drops in a rock-like gangue—the student is taught to identify the metal by the streak, "Tin-white when solid," and the cleavage "Perfect cubic when solid."

If there is a fault in the book it is the sacrifice of practice and real science to a system: streak

and cleavage are frequently or generally of importance, hence they are unduly introduced. Further, in reference to diamonds, under the heading, "Streak," we find "None," which rather reminds one of the story of a newspaper's stop-press news, "We stop the press to say there is no further news." To make "Halite" the main heading for rock salt, and "Cerargyrite" the main heading for hornsilver, suggests perhaps an over-devotion to the termination "-ite". Again, "Smithsonite" (p. 117) does not appear to us a very desirable leading term to replace the ancient calamine: still, the general scheme of the book is good, and with careful editing and better photographic illustrations, future editions may be much improved. Minerals give very full and good return for real skill in photography.

Microscopical Determination of the Opaque Minerals, as an Aid to the Study of Ores. By Joseph Murdoch, Ph.D., Geologist, Secondary Enrichment Investigation. First Edition. First Thousand. New York: John Wiley & Sons, Inc. London: Chapman & Hall, Ltd. 1916. 9*s.* 6*d.* net.

In the present volume the student will find a thoroughly well-laboured conspectus of that aspect of mineralogical research which corresponds to what is now known as metallography, and also to petrography; an aspect which the author appropriately terms "mineralography," and it may be that in future editions this concise term may be the leading title of the book, the present title then falling into place as a sub-title, or explanatory title.

"Mineralography"—if we may adopt and endorse our author's suggestion—is the art of judging of "opaque metalliferous minerals" by a study of a polished flat surface, while metallography is a comparable study of the reduced metals or their alloys. Petrography, on the other hand, involves the use of thin and more or less transparent sections of rocks which are not metalliferous in the broad and industrial sense, as distinguished from the more recondite chemical aspect.

We may, perhaps, put it rather emphatically that any person entering upon a serious study of mineralography will scarcely find any alternative to obtaining the work under notice, and in saying this we are perhaps giving the highest praise in our power to Dr. Murdoch's treatise.

It is to be clearly understood that Dr. Murdoch in no way claims to have originated that branch of technical discrimination or analysis of which he treats, as, like all worthy investigators and pioneers, he gives the fullest credit to those who have gone before. His concise summary of progress ranges from Berzelius (1814) to Charnot (1915); after which is a formal bibliography, including all papers on the subject which the author has been able to catalogue.

After this good beginning, the technics are concise but full. The old "lapidary's bench," as figured on p. 1205, Vol. III., of Holtzapffel's classic "Turning a Mechanical Manipulation," and as still used in many workshops, has no place in the present list of necessaries; but we have a figure of Sauveur's machine for polishing steel, in which four graded surfaces are all available in immediate sequence, a machine which will finish a specimen in an average time of six or seven minutes. The prospector is, however, told how he may operate—more laboriously, it is true—even at a remote mine, and with materials which may be carried in the waistcoat pocket.

Mounting, ocular examination as by the microscope, photographic recording under orthochromatic conditions, colour comparisons, needle-testing and reagent-testing, are all concisely, but by no means superficially, dealt with, after which the work is completed by elaborate tabulations and classifications, all clearly expressed, concise but nevertheless full.

A plate of four photomicrographs, plotted out in colours to indicate species, and with key colours, is not only instructive in itself, but also highly suggestive to the student. Here we have really good photographic rendering of exceptionally difficult subjects. A feature which may be mentioned is the considerable use made of cut-out leaves, after the fashion of an index book, so as to facilitate immediate reference to the various sections.

GENERAL NOTES.

Röntgen Society.—In a paper by Mr. C. R. C. Lyster, M.R.C.S., and Dr. S. Russ, on "A Biological Basis for Protection against X-Rays," the study of the protection of X-ray operators was approached from a somewhat different point of view from that usually adopted. In previous investigations the materials have generally been tested to ascertain what fraction of the incident rays are transmitted, while in this case an attempt was made to measure the total quantity of radiation received by the operator during, say, a day's work under normal conditions. For this purpose the operator carries a photographic plate upon his person, and at the end of the period under consideration the plate is developed. The density of the resulting image is compared with that of another plate termed the "biological basis plate," which has been exposed under standard conditions of radiation. A preliminary investigation enables the harmful effects of the standard source of radiation to be determined, and thus gives a meaning to the indication of the biological basis plate. Radium forms a useful source of radiation for practical purposes after the initial tests have been made, and it overcomes difficulties in the employment of an X-ray tube as a constant source. The effect of hard and soft radiation (twelve-inch spark to two inches) on the photographic plate was fully investigated, and it was concluded that for the same ionising effect the

hard and soft rays produced about the same photographic effect; the effect, however, varies with different makes of plates, and in consequence all comparisons must in practice be made with the same variety.—Mr. E. C. Head gave a detailed description, illustrated by numerous photographs, of a motor X-ray unit recently designed and constructed for use in Mesopotamia, etc. The Austin chassis was chosen on account of its low load-line, and the body was divided into two portions, one to serve as dark room, while the other contained the X-ray equipment. In operation a tent is erected at one side of the car, with the result that it is unnecessary to remove the coil or switchboard for use. Electric current is supplied from a dynamo run off the motor engine and from a small battery of accumulators, and is sufficient to render possible the production of short-exposure radiographs.

MIGRATORY BIRDS AND FOOD SUPPLY.—Mr. Clynes (Parliamentary Secretary, Ministry of Food) stated in the House of Commons on March 7th that the common and statutory law for the preservation of wild birds in Ireland was still in force, except that the Department of Agriculture had power, under the Defence of the Realm Regulations, to take action for the destruction of birds with a view to the protection of crops, and in the case of migratory wild birds for improving the food supply of the country.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

APRIL 10.—W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., will preside.

APRIL 17.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

APRIL 24.—MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons." The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India." The RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., will preside.

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m.:—

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana." SIR EVERARD IM THURN, K.C.M.G., C.B., will preside.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m.:—

J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day."

Syllabus.

LECTURE I.—APRIL 8.—Explosion and detonation—High and low explosives—Propellant power and disruptive violence—Requirements for military use—Materials and their sources—Ammonium nitrate and other nitrate mixtures and their military applications.

LECTURE II.—APRIL 15.—Other high-explosive mixtures and their uses—Chlorate mixtures—Nitro-cellulose and nitro-glycerine, and mixtures containing them—Military smokeless powders.

LECTURE III.—APRIL 22.—High explosives used for shell filling—Methods of detonation—Initiators of detonation—Tests applied to explosives—Miscellaneous.

SPECIAL LECTURES.

A special course of three lectures on "The Freedom of the Sea" will be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m. The first lecture will be given by Mr. GERARD FIENNES, the second by SIR FRANCIS TAYLOR PIGGOTT, LL.M., and the third by Mr. JOHN LEYLAND.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—March 29, 1918.

No. 3411. APRIL 5, 1918. Vol. LXVI

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,411. VOL. LXVI.

FRIDAY, APRIL 5, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICE.

NEXT WEEK.

MONDAY, APRIL 8th, at 4.30 p.m. (Cantor Lecture.) J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." (Lecture I.)

WEDNESDAY, APRIL 10th, at 4.30 p.m. (Ordinary Meeting.) W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

PROCEEDINGS OF THE SOCIETY.

THIRTEENTH ORDINARY MEETING.

Wednesday, March 6th, 1918; The RIGHT HON. FREDERICK HUTH JACKSON, M.A., in the chair.

The following candidates were proposed for election as Fellows of the Society :—

Anstruther, George Elliot, London.
Crabb, Thomas, M.I.Mar.E., A.M.I.Mech.E., Bengal, India.
Hepburn, Andrew, Horley.
Letcher, William Whitburn, London.
Mannell, John, London.
Mitchell, Ernest J., London.
Murray, Alexander Robertson, Calcutta.
Pardoe-Thomas, Bertie, J.P., Newport, Monmouth.
Pocock, George, London.
Poupart, John, Walton-on-Thames.
Powles, George Everett, Leeds.
Rama Varma Raja, His Highness, M.R.A.S., F.R.Hist.S., Malabar, S. India.
Robertson, Walter Henry Antonio, Bedford.
Stewart, John, London.
Tonkin, Wilfrid Wiseman, Lic.R.I.B.A., Potchefstroom, South Africa.
Ullyott, E., Leeds.
Walter, Francis Henry, Rio de Janeiro, Brazil.

The following candidates were balloted for and duly elected Fellows of the Society :—

Brocklebank, Rev. Clement Edmund Royds, London.
Drummond, George Henry, London.
Hobson, Arthur E., Connecticut, U.S.A.
Jou-lin, President Tsao, China.
Leverhulme, Lord, London.
Marshall, Herbert J., Gainsborough.
Metcalf, Henry E., London.
Mortimer, Engineer-Commander John Ernest, M.I.N.A., M.I.Mech.E., London.
Ogden, Henry Joseph, London.
Pantin, Carl Frederick Abel, 2nd Lieut. R.E., London.
Pantin, Herbert, London.
Quin, Lawrence Howard, London.
Rodd, Charles, Poole, Dorset.
Stephens, Mrs., London.
White, Charles, Aberystwyth.

The paper read was—

THE FOUNDATION OF INDUSTRIAL PEACE.

By A. H. PATERSON,
Secretary, National Alliance of Employers and Employed.

National safety now and national prosperity at the end of the war depend upon the preservation of industrial peace and its development upon broad constructive lines.

Everyone feels this, from Ministers of the Crown, great employers, and Labour leaders, whose sentiments are expressed on public platforms, to the toilers in factories and our soldiers on the battlefield, whose sentiments seldom find any public expression at all.

Unfortunately, while we all desire industrial

peace for our country's sake—even the reactionary who would like to see "unrest" suppressed by the machine-gun, or the anarchist whose panacea for all ills, industrial and other, is to turn Society upside down—yet each of us wants most of all a particular kind of peace of his own.

The class-conscious Socialist and disciple of Karl Marx is as anxious as anyone that British trade should compete successfully with foreign rivals after the war, but he holds it to be his first duty, whatever may betide, to strive for the transference of ownership of capital from private hands to those of the workers in each trade who, he maintains, alone should control production.

The State Socialist, and certain functionaries who have taken office lately in Government Departments, are sworn foes of Prussian Bureaucratic tyranny, but they believe that the chief needs of this country during the reconstruction period will be control, and even management, of industry by the State, and the appointment for the purpose of intelligent Government officials on a permanent basis and with plenary powers.

The trade unionist is ready to agree that foreign competition and the international market price of goods will affect wage rates in the future, and that no premium should be put upon inefficiency or slothful labour, but he considers it to be his primary duty to get out of employers on all occasions the highest possible pay obtainable for all members of his union.

The average employer, on the other hand, though agreeing with the principle that workmen should receive a fair share of the proceeds of production, and that all who labour should be paid a living wage, is nevertheless convinced that the direction of business must remain conclusively in his own hands; and though he is in favour of Labour becoming more intelligent and better organised, and even better educated, yet if you press him he will admit that he prefers workmen who leave the thinking to him to those who think for themselves.

The so-called "capitalist," too—that is to say, the man whose income is derived from dividends on invested funds or real estate—though quite alive now to the need of harmony between "Capital and Labour," and especially anxious that there shall be no strikes or lock-outs where he has business interests, demands from the management of his companies as high a dividend as business exigencies permit.

Then the consumer: he, or rather she, is a patient creature nowadays, and is often secretly proud of the sacrifices which the war has forced upon her; but when the war is over and tradesmen compete for her custom, it will be no longer a question of patriotism, but of cheapness. The producers, she will say, have had their day. It is now her turn. And whatever happens prices must go down.

Last of all, and most important, we have to reckon with the point of view of the men in the Army and the men, and the women, in munition works—especially those who do not belong to trade unions, and who will have no "trade" to return to when the war ends.

It is not easy for us at home to realise what soldiers who have been separated for one, two, or three years from industrial life feel exactly in regard to the future of industry, and it is still more difficult to form conclusions as to what they will say and do when they are no longer needed on the battlefield.

But there are certain things we know—those of us who have been in close touch unofficially with the men in France and on home service. We know, for instance, that though official departments propose, sensibly enough, that the Army shall be gradually demobilised, and only those men released at first whom their country wants to fill up industrial gaps, our soldiers, one and all—skilled artisan and casual labourer, cook and costermonger—are possessed of a fixed determination that the moment peace is signed they will all come home at once.

Such a determination is, of course, unreasonable. It is almost immoral in the eyes of official persons who have never known the hunger for home-life which has become almost a madness to hundreds of thousands of our civilian Army, and which, like all madness, may become extremely dangerous unless it is gently and humanely, as well as firmly, dealt with. And that determination, bear in mind, is growing stronger and more widespread as the war drags on.

There is nothing inherently revolutionary in this attitude of our soldiers. The lads are just mortally tired of it all, and though the way in which they talk about high authorities of Government, or even of Parliament, shocks many people, it is only a habit they have. Soldiers do not trouble themselves about class-consciousness, nor do they claim ownership of capital, or even yearn for the sharing out of real estate and the nationalisation of the land; while State control of any kind receives short shrift if mentioned in their hearing. It has held their lives in its grip all these weary years, and they have had

enough of it. They will accept anything the State may give them and take it as their right, but they will never consent to be under its control again.

They just want to get home—that first. Then they want a rest, then to get a job, and after that a peaceful and a quiet life for ever and ever more. But they want all this in a way which, if they are thwarted or disappointed in any reasonable expectations, and begin to feel their country and its rulers have forgotten them, and having exploited some of the best years of their lives, and made them endure misery and hardship unspeakable, and the risk of death itself, are going to "turn them down," as they would say, and leave them to struggle like blind kittens in the whirlpool of industrial competition at the end of the war, they will be far more dangerous to the peace of the realm—not to mention that of industry—than all the anarchists and "down tools" men to be found in these islands at the present time put together.

Of course, no one wishes or intends to turn them down. All of us, no matter what our views may be of a future social and industrial State, are united in a resolve to see justice done to those but for whom our State would have no future at all. We are apt, however, to forget or, at least, very much under-estimate, the sacrifices which will have to be made, and the difficulties which must be overcome, to give our fighting men what they need when their task is done.

This brings me to the point of view of the munition workers.

The Minister of Munitions stated the other day that those he employed numbered from two to three millions. He was well within the mark. Now most of these workers will be demobilised and return to their homes within a few weeks or less of the day peace is declared. What is to be done for them and with them?

They are asking this question with much anxiety. They feel that public opinion, easily aroused for the soldier, will not trouble itself much about their fate. There will not be much sentimental feeling, they know, for civilians, the majority of whom have earned wages many times the amount of a soldier's pittance without having had to risk their lives in the process.

This is true, but there is another side to the question which the soldier who is far from home sees very clearly.

The most urgent need of the country in industry, when the war is over, will be efficient workmen and workwomen to manufacture goods for home and foreign markets. It is the common opinion of everyone engaged in trade and commerce that maximum output, and maximum output alone, of all those articles with which this country can supply other countries, will enable the nation to hold its place in the world's market, and meet its liabilities.

The men in the trenches now cannot at first be as efficient for very many kinds of skilled employment in factory or workshop as those who have been there throughout the war. Hard manual labour and all kinds of unskilled work the average soldier will be well fitted for; but, in a strictly industrial sense, and on a business basis of supply and demand, the better paid jobs when demobilisation comes will be taken up by munition workers, and it must be admitted, that as far as production is concerned, this will be to the advantage of our industrial position.

There is the further point that the munition workers will be on the spot ready for immediate transference to reconstructive work. It is this fact, above all others, which causes the soldier to blaspheme when high officials in this country lay stress upon a plan of gradual demobilisation. If, in addition to being held back too long from their homes and dear ones, the men of the forces find that preference in re-employment is being given to the men and the women who took their places in industry when they—the soldiers—were forced out into military service, there will be trouble of the most serious kind.

It is not within my province to suggest to you to-day practical ways and means for meeting this particular dilemma. Our concern now is to consider whether any sure and stable foundation can be laid down on which may be built up any industrial peace sufficiently comprehensive, effective and permanent to solve the problems and meet the dangers I have endeavoured to indicate.

I believe that such a foundation can be established. I would even go so far as to say that the power of creating all that is needed lies ready to hand. If all forces engaged in industry were to seek alliance with one another for an improvement in those conditions of industry which all alike concur in feeling to be of vital importance, not one of the differences that exist between them, and probably always will exist, would drive them into war.

I shall be told that this is an impracticable proposition. Many people, indeed, have said that it is quite impossible. I would ask all such people whether if, in 1913, those achievements

of this country in the war due solely to employers and employed, and Government officials too, working in closest alliance, had been described as possible, any business man of that day, or employer or leader of Labour would have believed it? Alliance between employers and employed is not only possible, but it is being established. It is a tiny seed at present, its main achievement so far the creation of confidence and mutual trust among representatives of certain employers' associations and trade unions and the members belonging to such bodies. It has, in addition, created an atmosphere of friendliness among local groups of workmen and employers in some large industrial centres. Last, but not least by any means, it has begun to cause serious annoyance to the more extreme and bigoted advocates of industrial division, disruption and dissolution.

All that is needed now is that the people of this country, irrespective of class, politics, and divergent points of view over the relative position of "Capital and Labour," shall realise the importance of peace in industry, now and after the war, as they have realised the need for the struggle with Germany, and shall be ready to make some part—not a great part—of the sacrifice to obtain it which they are making so heroically to beat Prussian militarism to-day.

I know everyone is tired of sacrifice. All are looking forward to a brighter world when we have won through, and to the realisation of those social ideals which have to be held in abeyance while the common enemy remains in the field.

Yet if it is realised that none of the ideals we cherish can possibly be attained unless there is peace between Capital and Labour, the very determination in our hearts to create better things for ourselves, and our class, will be an incentive to laying a foundation for our country of an industrial peace which it shall not be possible for irreconcilables of any kind to break.

I think that throughout the nation to-day a feeling is steadily growing that at whatever cost to private or sectional interests a way must be found to consummate such a peace.

I speak from personal experience. It has been my duty, and I may say great privilege, to address frank and thoroughly informal conferences of employers and of workmen in great manufacturing centres in the North, the Midlands, and South Wales, and to hear expressed the most candid views and opinions upon the causes of industrial disagreement and strife. I have also attended public meetings where men and women of all classes have been addressed by representatives of both sides, standing together on the same platform.

At these conferences and meetings, especially the informal ones, held at such places as Liverpool, Manchester, Birmingham, Newcastle, Sheffield, Cardiff, and Swansea, Worcester, and Gloucester, I have heard the hardest things said and the roughest heckling administered to men like myself who took up the cudgels for peace and goodwill.

But what has struck me most on every occasion has been this: Not one speaker had a word to say against the principle of whole-hearted co-operation between employers and employed to deal with dislocation of industry, and the vital problems of demobilisation and reinstatement of soldiers and munition workers after the war. Where they differed and argued against one another, or against me, was in regard to the means by which effective co-operation should be brought about. Another thing—most significant, perhaps, of all—the cause of any objection to joint action between managers in the counting-house and labourers in the workshop to improve business and raise the condition of the workers, was always suspicion of the motives of the man on the other side which, when traced to its source, proved to be nothing but sheer ignorance of his real attitude and intention.

Again and again, after long, hot arguments, and the use of language quite unprintable, it has been just those men who at first were most opposed to any approach to working hand in hand with men of a different class who became the keenest and most determined apostles of a shoulder-to-shoulder policy of men of all classes, be their social standing what it might, so long as they proved themselves to be men of honest goodwill.

Another lesson I have learned. Industrial peace cannot be founded upon "co-operation" merely. It must rest upon alliance for a common purpose.

Would "co-operation" in our Army hold the Germans back? Only comradeship, tried and true, comradeship on an equal basis—such as men feel when hunting a tiger in the jungle on foot—will found any peace in industry in this country worthy of the name.

This is what we want and must have to win industrial peace. That is why I began by suggesting the necessity for sacrifice. There is no difficulty about sacrifice if there is comradeship, but nothing less potent will inspire it.

Let us now consider how this comradeship, which I hold is the true foundation on which

industrial peace can be built, can be created and begin its work.

I claim no originality in emphasising the need of comradeship among members of the classes and masses; the employer and the workman; the producer, the consumer, and the Government official.

The National Alliance of Employers and Employed, which I have the honour to serve, was actually the first body of men which laid down in public more than a year ago the urgent need of such comradeship as I have described among employers, employed, and the Government, to deal with demobilisation problems. Further, I have not yet seen any conference of Labour or of employers, or both together, or recommendation made on the subject by any Government Committee or Commission since the National Alliance put forward its programme for demobilisation, in December, 1916, which has not taken very large bites out of our programme, sometimes even reproducing the whole of it without, of course, any acknowledgment whatsoever.

But that is a matter of no public importance. It is, from a national standpoint, to the good that the pronouncements of a group of private citizens should have been adopted *en bloc* by the Industrial Unrest Commissioners (after investigations of their own); by the Whitley Committee; and voluntary organisations such as the Industrial League for improvement of relations between employers and employed; and, the latest creation of all, the Industrial Reconstruction Committee.

I am in no way concerned here with the claims of any individual organisation, least of all my own, to recognition. The point at issue is how we are to found the peace we need—not who is to be the instrument.

To decide this question we must go far beneath the surface of things. The greatest danger of all to such a cause as this is the tendency in human nature to like window-dressing and neglect the real substance for the obvious shadow.

We have before us, for instance, the Whitley Report proposals for joint industrial councils of employers and employed in each organised trade. Excellent, sound, and practical proposals they are. I wish them every success. But I cannot myself accept them as a foundation for industrial peace. They are part of the building above.

Masters and men in several large trades have already been in the habit of meeting together on trade questions. Their meetings, however, have not resulted in the comradeship we need for industrial peace, or even in any particular good-will. The reason is not far to seek. When employers and workmen of a trade meet together on trade matters they are simply there as men of business to discuss business problems —the men to get the best they can in their own interests, the employers in theirs. Men may meet one another on a business basis of this kind for years—without becoming even friends. I know that the Whitley Recommendations suggest that subjects outside ordinary trade questions shall be dealt with by these committees, but I fear that an atmosphere of business, not of comradeship, will prevail. Now, industrial peace will never be secured upon a foundation of business relationship between Capital and Labour.

On the other hand, the establishment of joint trade committees is an essential part of any structure of industrial co-operation.

The foundation to this can only be laid by the establishment in each industrial centre or area of a district committee or council for purposes partly industrial and partly social of employers and workmen in equal numbers, representing employers' associations and trade unions of all trades and occupations—each district committee or council so formed to be represented upon a central and national council, which, through an executive committee, consisting like the local bodies of employers and employed of equal numbers, shall co-ordinate and mould into a combined national force all that given in service or authority by the joint local industrial forces.

With these committees or councils, local or central, of employers and workmen, there must be associated men and women of all classes, who may elect representatives on the committee to serve with the employers' and workmen's representatives, and by their associate membership—which should number hundreds of thousands as the objects and motive of the movement became known — give moral and financial support capable of becoming a powerful source of strength and stability to their industrial comrades.

The work of this union of forces both industrial and individual must be confined, as far as possible, to promoting those general objects which are common to employers and workpeople of all trades, and the members of the community at large who cannot be considered to belong to either side.

Among these are satisfactory housing of the industrial population; the proper conditions of lighting, heating, etc., of all workshops and

factories, together with "welfare" work in all its branches; education, especially of a non-technical kind; the status of women in industry and the future for women's work; the main principles on which demobilisation and reinstatement both of munition workers as well as men of the forces, should be carried out; the very vexed and difficult questions of administration of Employment Exchanges, both in connection with demobilisation and in the future as a permanent system; the infinitely important and equally difficult subject of imparting knowledge of the business of a firm or company to those who labour in the works, and giving representatives of such works real power in regard to management, so that a partnership in point of feeling, at least, may be established between each employer and his men—without, of course, weakening trade union organisation on the one hand, or, on the other hand, undermining discipline, and the rightful authority of the directorate of the company.

Most important and, in the face of all that is to come at the end of the war, absolutely vital to industrial peace, will be the securing of safety for both sides in times of bad trade. The workmen I have seen over these matters, place far more stress upon this point than on any of the others. One, a man of extreme views, went so far as to say that if employers and workmen could stand shoulder to shoulder in this matter, nothing more need be done to ensure industrial peace and goodwill.

It is indeed a problem which only comradeship in the closest sense can solve, for it means much mutual sacrifice and give and take. It is one that can never be settled piecemeal by separate trades boards. It is one which, if, taken in hand by Governmental authorities alone, will wreck everything, causing heartburnings, favouritism, pauperisation, and a general demoralisation of all workmen or employers taking any part in it.

It may reasonably be questioned whether a voluntary organisation strong enough to carry out such a program as I have sketched can possibly be set up in the midst of this war. Undoubtedly it will be a difficult task, especially as several powerful interests will not look favourably upon the establishment of a voluntary combination of this kind. But I would venture to reply in Cromwell's well-known words: "Gentlemen, it is of necessity and therefore to be done."

It is of necessity that adequate means shall be devised to bring men of all classes to work together for the general betterment of industrial conditions on a voluntary basis. That and that alone is a sure foundation, I venture to repeat, on which to build up the work of the Whitley Committees, Government Resettlement and Reconstruction Committees, Employment Exchange Boards, Trade Boards, and what not, and to make them effective for the purposes for which they are assigned.

If such a foundation is not laid, and speedily, the disruptive forces now at work, political, social and bureaucratic, are such that, though we shall, I believe, win through our struggle with the Central Powers, yet we shall be beaten utterly afterwards on industrial issues by our own Allies—especially America—by neutrals, and finally by Germany herself.

And it is to be done, for already the ground has been tilled and seed sown in many a city and town, both in England and Scotland. In these places and in London, men—employers, Labour men, and men of business—who up to a few months ago were entire strangers, ignorant and indifferent to one another's thoughts and ideals, are now working day by day in the closest companionship for just this one object—the construction of a foundation for industrial peace

Each day this number grows. Also the number grows of men of every class and from all parts of the country, joining as associate members, from great Companies and Trade Unions which send £100, to workmen who contribute 1s. annually, which entitles an associate member to be entered on the membership roll.

It is yet only a small band in point of numbers, but a very hopeful one—great in faith and courage; and, I believe, in all earnestness, that it represents forces in this country which will in very truth bring peace into our industrial world and be the foundation of true comradeship and brotherhood among the men who lead that world, not only during the reconstruction period but for all time.

DISCUSSION.

THE CHAIRMAN (the Right Hon. Frederick Huth Jackson), in opening the discussion, compared the paper with that read before the Society recently by Lord Leverhulme. Lord Leverhulme gave the conclusions he had arrived at from his experience as a large employer of labour, while the author of the present paper gave the conclusions he had arrived at from close touch with employers and workmen all over the country, and with soldiers home from the front, and the extraordinary resemblance between those conclusions was most remarkable. Lord Leverhulme advocated shorter

hours of labour and higher wages, and had established a system of profit-sharing in his own works, while the author did not particularise but confined himself to advocating the adoption in industrial life of that spirit of comradeship which existed to a striking extent among the soldiers at the front. Both Lord Leverhulme and the author insisted on the absolute necessity of introducing a different atmosphere into industrial relations, the substitution of a spirit of mutual goodwill for the spirit of mutual distrust and suspicion which prevailed in this country in the relations between employers and employed just before the war. He cordially agreed with all that the author had said on that subject, and believed that if this country could secure the whole-hearted co-operation of employers and employed after the war its future greatness would be assured. Some people might say that the members of the National Alliance of Employers and Employed were idealists aiming at the impossible, but his answer was that Lord Leverhulme and many other large employers of labour, as well as leaders of representative and important trade unions, had expressed their approval of the movement initiated by the Alliance, and were supporting it with their influence and with their money. If the war was followed by serious labour troubles, such as those that were threatening just before war broke out, and if this country returned to the conditions which prevailed in the summer of 1914, then its future was indeed a gloomy one, and it was surely worth while for all ordinary citizens who had no direct interest in the relations between capital and labour to do their best to avert such a contingency. The National Alliance of Employers and Employed fully realised the difficulties of its work, but it was composed of a determined and enthusiastic body of men, and if those men could indue the public with some of their determination and enthusiasm the success of their work would be assured. He would like to conclude his remarks by two quotations. The first was a remark made by the late Earl Grey, one of Great Britain's overseas administrators, who said: "I am certain of this: character is poisoned by self-interest. I do not care how good a man is; when it is his interest to cut down wages or to give as little of his skill as he can, that man will infallibly lose his sense of justice. He will deteriorate. Give him another principle, make him feel that he owes a duty to his fellow men, convince him that he is responsible for the welfare of others, and all that is good in that man's nature will grow and respond." The other passage he wished to quote was from the great patriot and statesman, Edmund Burke, who said: "Magnanimity in politics is not seldom the greatest wisdom, and a great Empire and little minds go ill together." If those remarks could be impressed upon the mind of every person in this country, that new atmosphere would be created which was so essential if the serious problems which would confront this country when the war was over were to be successfully solved.

Mr. Basil E. Peto, M.P., said that, although he appreciated the aims and objects of the author and the Alliance of which he was Secretary, to his mind there was a want of definiteness about the Alliance's programme of comradeship which might perhaps prevent it doing all that its promoters intended. He was rather disappointed to hear the author state that co-operation in business relations would not produce comradeship, because he thought that the best possible comradeship in industrial life was produced by the feeling that employers and employed were working together for a common object, and that both would reap some reasonably fair rewards from their common effort. Co-operation in its widest sense, by which the workmen had some share in the results of their industry in addition to their wages, was the most potent force in the establishing of industrial peace. The author had stated that the object of the trade unions was always to obtain the highest possible pay for their members. During the war so-called pay in pounds sterling had doubled, and the State, when it wanted to borrow, paid about twice the rate on interest on capital that it paid, say, twenty years ago, and as everything people wanted to buy now cost twice as much as it did before the war their spending power was very much in the same position as it was then. For very many years the people of this country, encouraged by the Bank Charter Act, had been worshipping the pound sterling: the working-classes were not to blame for that attitude, as they were only following the example of people who were supposed to know more about finance. What was really essential now was to make everyone realise the truth of the author's statement that the maximum output was the one thing to be aimed at. The working-classes must be shown that the man was the real benefactor who enabled them to produce more, that it was only by increased production that increased consumption could be brought about, and that the present vicious circle of increase of wages and increase of cost did not benefit anyone. He noticed that the author referred to consumers as constituting a separate class; but every producer was also a consumer, and he did not believe there were any consumers who in the long run could consume if they did not also produce. The conditions necessary for industrial peace and increased production were, first, improved processes of manufacture; secondly, that labour must have a direct interest in the results of their individual effort; thirdly, that there must be absolute security for the possessions of each individual, apart from absolutely necessary taxation; fourthly, that there must be opportunities for individual advancement, both commercial and educational. It was also of great importance that the finance of the country should be so arranged that a far better system of credit could be established and productive enterprise made, as in Germany, a matter of the first importance.

Mr. Harry Dubery (Secretary, Post Office Federation) did not agree with the statement that trade union leaders taught their members that the chief object of trade unionism was to secure increased wages. The ordinary trade union worker had met with certain obvious experiences which taught him certain doctrines. With regard to the question of maximum output, for instance, unless that maximum output was combined with high and increasing wages, and with absolute security of tenure, no trade unionist would approve of it, because if maximum output was combined with low wages it meant that a large stock of goods was produced which in time created a surplus, which, owing to their low wages, the working-classes could not buy, and they were automatically thrown out of work because the maximum output had produced an over-stocked market. The working-man, therefore, came to the conclusion that if he worked too hard and produced a great deal he would be thrown out of work more quickly than would otherwise be the case. Those facts were not taught by trade union leaders, but were acquired by the men through their actual experience. If conditions could be created whereby a man had security of tenure, and knew that if he worked hard he would not be thrown out of work, and also knew that some of the excess of commodities created would come back to him, a different atmosphere would be produced, and he would agree to the doctrine of maximum output being necessary. The author suggested that Trade Boards would not necessarily produce the atmosphere he wanted. That was true, but such Boards were a very excellent preliminary. Amongst the group of trade unions which he represented, increased wages were formerly obtained by great public meetings, press campaigns, lobbying in the House of Commons, talking about strikes and producing an atmosphere of unrest—all of which made for the opposite of maximum output. Now, however, Boards had been set up—on one of which he was sitting at the present time—which consisted of an independent chairman, three representatives of the employers, and three representatives of the trade unions, and which discussed the necessary wage increases that might be required. The creation of those Boards had prevented in the last two years at least three periods of agitation and unrest in the Government Service. Immediately after the termination of the war the Government proposed to build another large Post Office which they intended to be the best planned and best equipped Post Office in the world, and they had formed a committee to consider its design and scheme of working, for which the trade unions had been asked to nominate representatives. By working together in that way the basis of industrial peace was secured. On all Wage Boards and other committees of that kind both sides must sink their personal desires and put first the social betterment of the country, and in that way the right atmosphere would be created for the establishment of industrial peace.

Mr. E. W. Mundy (Secretary, Labour Co-partnership Association) agreed with Mr. Peto that the idea of comradeship put forward by the author was rather intangible, and he would have liked him to be a little more definite as to how industrial peace could be brought about. The Association he represented had for more than twenty years preached much the same doctrine as that which the author now put forward, but instead of calling it "comradeship" they called it "co-partnership." They had adopted the word "co-partnership" as meaning a partnership between the employer, representing capital, and the employed, and had started out on a rather material basis, namely, profit-sharing, in order to get one common interest between the employer and the employee on which they hoped to build higher and nobler interests between the two parties. Under the co-partnership scheme the worker was given his share of the profits in capital, so that each worker became a capital-holder or a partner in the business in which he was engaged, and he was also given a share of control. The author said that when the two parties could be induced to sit round a table and discuss their difficulties, in nine cases out of ten a solution could be found, and that was what the co-partnership movement had been advocating for many years. In the South Metropolitan Gas Company such a committee had been sitting for a long while, and there were similar committees in various works all over the country, and he hoped more would be formed through the agency of the Whitley Report. He thought the committees advocated by that report would be far stronger if the individual workers upon them were also shareholders and had a pecuniary interest in the business. He would like to ask the author whether the National Alliance of Employers and Employed had made any attempt to work out a real science of wages. There was no such science in existence at the present time to his knowledge—only the old idea of the law of supply and demand.

Mr. Robert True did not think profit-sharing could apply to an industry as a whole. He knew of a committee which had been in existence for the last seven or eight months in connection with a certain business, and which was composed of representatives from various departments of the works, whose duty it was to consider improvements, complaints or grievances, and bring them before the management, thus giving the men in the shops a share in control. He could not think that the average working-man desired or had a right to a seat on the board of directors, as some people suggested. The workmen wanted comfortable working conditions and to know that if they brought forward suggestions they would receive consideration. In the case of the committee he had mentioned, the remuneration for the improve-

ments suggested was based upon the actual saving they brought about, and the suggestions, which were brought forward monthly, were increasing in number and in value. Profit-sharing was, he thought, only applicable to individual businesses that could look forward with certainty to making profits, for in a business where profits were uncertain it was very difficult to convince the men that they had not been made. He had a great deal of sympathy with the author's proposals, and believed they were going to be successful.

Mr. E. O. Greening said he had had the pleasure of working with Mr. Hughes, the Rev. Charles Kingsley and others in founding a number of industrial co-partnerships in connection with the co-operative movement. The first report of those was compiled in 1883 and the most recent in 1916. There were now seventy societies scattered all over the Kingdom in all kinds of trades and industries, in which the workers, the capitalists and the consumers had joined hands, and in which the profits were divided between them and control was shared among all parties. In all those workshops there had been industrial peace, with no strikes and no lock-outs. In 1883 their output for each £100 of capital only amounted to £160, but in 1916 they had increased to £230. The growth had been a steady one, increasing year by year. The profit on the capital employed had also increased from 8·62 per cent. in 1883 to 17·10 per cent. in 1916. Therefore the industrial peace which had prevailed in those workshops, together with the increased zeal, economy and industry which were brought into the work, had added 50 per cent. to the output and doubled the amount of profit between 1883 and 1916. Would the author say that the workers who could produce that remarkable result were to be content with merely a sentiment of comradeship being established between them and the employers? Supposing that men working eight hours a day were instead to work nine hours and receive no extra wages, if at the end of the year there was a surplus the employer would probably say that the men were to be paid for the extra time they had put in, and the results which had come from that extra time. Was it not the same thing if the men, without increasing the number of hours, put nine hours' work into eight hours, and should they not share in the results? There ought to be some definite, equitable arrangement by which the worker should receive a share of the profits produced by his extra exertion.

Mr. Paterson, in replying to the discussion, said that "co-partnership" was in one sense a stronger word than "comradeship," but its commonly accepted meaning had made it something which was not strong enough for what was really necessary as a foundation. He was only speaking of the foundation and not of the building. If Whitley Committees, Trade Boards, and the Committees such as Mr. Dubery had mentioned were not going to be built on his foundation, then that foundation was of no use at all, but the type of committee recommended in the Whitley Report only dealt with organised workers, who constituted only about 4,000,000 out of the total workers of 18,000,000, and therefore was not capable of actually being a foundation. The criticism had been made that the proposals put forward in his paper were rather intangible, but again he must say that he was only dealing with the foundation—which was that employers and workmen in equal numbers and representative of all trades should meet together, district by district, to discuss certain matters which affected all the men, such as housing. Those conferences would form a foundation of comradeship, and they themselves should work out a science of wages when they had agreed on the foundational subjects such as those particular matters which required attention in their own neighbourhood. In one district in the Midlands where a committee had been definitely formed, it started by taking up workshop conditions, because in that neighbourhood workshop conditions were very bad. The committee was going to visit every workshop in the district, and make employers whose workshop conditions were defective understand that unless those conditions were improved they would not only have labour against them but also the leading employers in the neighbourhood. He thought the impression made by that process upon every employer and workman within that district would enable the Whitley Committees and Trade Boards there to do infinitely finer work, and would enable the co-partnership principle, of which he was entirely in favour, to be set in operation more easily. The scheme outlined in the paper was purely a foundation on which to build.

On the motion of the Chairman, a vote of thanks was accorded to the author for his interesting paper, and the meeting terminated.

CHINESE WOOD-OIL INDUSTRY.

One of the most important of Chinese products —and one for which Hankow acts as chief exporting centre—is t'ung-yu, or wood-oil, and the following interesting details of the industry are from a report by the United States Vice-Consul at Hankow.

Wood-oil is obtained from two varieties of *Aleurites*, a small genus of the *spurge* family. Each variety has rather sharply defined boundaries—the mu-yu shu, or wood-oil, tree being found for the most part in the southern provinces, while the t'ung-yu shu, literally tung-oil tree, is confined mainly to Central and Western China. By chemical analysis the oils of these two trees are found to be practically the same, but the t'ung-yu shu is of far more importance

because of its greater hardihood and wider distribution. Fully nine-tenths of the so-called wood-oil exported from China is made from this variety.

The mu-yu is generally found in the Province of Kwangsi, near the city of Wuchow, which also acts as its chief market. Some of the oil is shipped to Hong-Kong, but the trade is not large.

The Yangtze Valley, especially in its upper reaches, is the territory in which the t'ung-yu tree flourishes most freely. The hilly country found in the gorge region, and, in fact, all the land from Ichang westward to Chungking, is particularly adapted for its growth. The plant is most often found on rocky hillsides, thriving on the poorest of soil so long as the annual rainfall is not less than 29 in. and the altitude not greater than 25,000 ft. The tree seldom exceeds 25 ft. in height, is rather ornamental, and has a great profusion of blooms in April. The fruit is about the size of a small orange, and contains three to five seeds not unlike shelled Brazil nuts in shape, although resembling more nearly the hickory nut in size.

The nuts are always gathered before maturity. As they are covered with a husk they are either parched in iron pans or sieves over a fire, or else covered with straw or grass, under which fermentation takes place in the thin fleshy part of the fruit, thus allowing the nuts to be easily removed.

The methods employed for extracting the oil, although crude, are effective. After the seeds are removed from the husks they are placed in a circular stone trough, where they are crushed by a stone roller drawn by a buffalo, cow, or ass. The pulverised meal is partially roasted in shallow pans, then steamed over boiling water, the product meantime being placed in wooden vats fitted with wicker bottoms. The nuts are next placed in steel frames with straw as an outside container. The frames are arranged on edge in a press and pressure is applied. This is usually accomplished by means of a system of wedges which are driven in one after another by means of a huge battering-ram until the brown, watery, and odoriferous oil is crushed out into the vat below. As a rule the oil is then slightly heated and strained through a coarse grass cloth. (If the heating process is carried too far the oil becomes dark brown instead of retaining its desired light yellow colour.) The product is then placed in wicker baskets lined with varnished paper, and is ready for shipment. As a rule, the oil yield is about 40 per cent. of the original weight of the kernels. The refuse matter, which is in the form of cakes, is used as a fertiliser.

In the vicinity of Hankow the native dealers allow the oil again to precipitate, drawing off the clear liquid and selling it to the foreign exporting firms. The residue is then sold to small dealers in Wuchang and Hanyang, who once more skim the oil after a further precipitation process. The oil is then sold to the native boatmen for use on their craft.

About the only variation in the above method of oil extraction is that in cold weather, when the oil congeals to a grease stage, it is necessary to heat the mass slightly in order to allow precipitation to take place. This is usually accomplished by steam coils being placed within the containing tank. Under this treatment the product soon liquefies, the foreign matter drops to the bottom, and the clear liquid is drained off through stopcocks placed just high enough to avoid the thick, muddy sediment at the bottom.

T'ung-yu is widely used throughout China as a paint oil for outside purposes. It is reported that as a drying oil it excels even linseed oil. One of its greatest local markets is found among the native boatmen, who never paint their boats but coat them with the cruder grades of wood-oil, which not only gives the woodwork a bright, lustrous finish, but also acts as an excellent preservative. When certain mineral substances known as t'utzu and t'o-shen are added to the wood-oil and the resulting mass is heated for about two hours, a varnish called kuang-yu is produced, which is valuable as a waterproofing substance when placed on silks, pongees, and similar articles.

T'ung-yu is also used as an adulterant in the manufacture of lacquer varnish, as an illuminant, and as an ingredient in concrete, and when mixed with lime and bamboo shavings it is used by the natives in caulking their boats. The so-called Chinese or Indian ink is made from the soot resulting from the burning of the oil or the fruit husks. The product is also used as a dressing for leather, in the manufacture of soap, and as a varnish for fine furniture. It is chiefly used in foreign countries for the manufacture of varnish from cheap gums. Other oils require a higher and more expensive quality of gum in order that the resulting varnish be of equal grade. This feature, together with the rapidity with which wood-oil varnish dries, has caused the demand for the product steadily to increase.

The growing importance of wood-oil has led countries other than China to look into the possibilities for the culture of the tree within their own domains. The United States in particular has made rather extensive investigations along these lines, and it is reported that soil and climatic conditions in some of the southern States are such as to permit of the tree's growth and cultivation. Certain it is that the product is of sufficient importance to warrant consumers in carefully investigating its future possibilities.

The quality of the 1916 output of wood-oil was below average. This condition was due in large measure to the fact that adulteration to a greater or less extent was practised by the native producers during the entire year. Especially was this so during the period of high market values.

As a rule, tallow seed and peanut oils are the adulterants used, although sesame, rape, and poppy-seed oils are also utilised when their market values are not prohibitive.

The fruit of the t'ung-yu shu, from which wood-oil is made, usually matures about the middle of October, but last year rains prevented the gathering of the crop until nearly a month later.

Practically the entire output of wood-oil is produced in the provinces of Szechwan, Kweichow, Hunan, and Northern Hupeh, their percentages of output in the order named being 35, 25, 25, and 15. Hankow is the chief exporting centre, shipping, in 1915, 34,246 tons of oil, valued at 5,748,490 taels (about £730,000), or over 90 per cent. of the export for the whole of China. Wuchow is the only other exporting centre of any importance, but it in no way rivals Hankow, as its total shipment during 1915 was but 1,880 tons, valued at 315,767 taels (about £40,000). The following table shows China's shipments of wood-oil to foreign countries during the years 1912–15 :—

Exported to	1912.	1913.	1914.	1915.
	Tons.	Tons.	Tons.	Tons.
United States (including Hawaii)	18,328	18,526	15,832	12,852
European countries	13,018	7,311	8,036	3,040
Other foreign countries	3,343	1,761	2,296	2,580
Totals	34,689	27,598	26,164	18,472

China's output of wood-oil has decreased over 45 per cent. during the four years 1912–15, whereas the demand, especially in the United States, has been steadily growing. It is believed, by those most closely in touch with market conditions, that upon the resumption of normal conditions in China and in Europe the trade in this product will reach unprecedented levels.

JAPAN'S INDUSTRIAL DEVELOPMENT.

One of the most noteworthy features in the commercial history of the last three years, says a correspondent in the Commercial Supplement of the *Times*, has been the rise of Japan as an industrial nation. The first effect of the war on trade was to oust Germany and Austria from the world's markets; then the conquest of Belgium put that country out of the running; and, later on, as the struggle made greater and ever greater demands on the industrial resources of the Allies, France, and even the United Kingdom, found themselves unable to satisfy the demands of the overseas markets for all classes of goods. The result has been that those nations which have been able to turn their full attention to industrial pursuits have increased their foreign trade by leaps and bounds, and one of the outstanding examples of this is Japan.

In 1913 Japan's exports were valued at £64,264,000; by 1915 this figure had increased to £71,453,000; and in 1916 to £114,000,000, an increase in three years of 77 per cent. Moreover, the improvement is still going on, for in the first six months of last year the exports were valued at £71,373,000. Presuming that during the remainder of the year trade continued at the same rate—and with America definitely engaged in the war Japan may reap a still greater harvest—the figure for 1917 will be something like £140,000,000, or more than double that of the last pre-war year.

Of course, a certain proportion of this enormous increase is accounted for by inflated prices, but higher prices do not account for the whole of the increase, as will be seen later. The fact is that Japan has recognised her opportunity for industrial and commercial expansion, and has seized it. The Japanese are a clever, energetic, resourceful people, with a special genius for learning from the example of other nations. With an abundance of cheap labour and cheap power derived from the many waterfalls of the country, and helped by the absence of low-priced German goods from the market, Japanese manufacturers have been able to turn out in certain lines goods which, at the price at which they are sold, will probably be able to compete with any the world can produce.

That the Japanese manufacturers believe in themselves is shown by a recent announcement in the native press that the Tokio Gas and Electrical Company, which, besides its ordinary manufactures, is already engaged in the manufacture of incandescent mantles, galvanised iron and enamelled ware, is now increasing its capital from one to three million yen (£102,000 to £306,000). The new capital is to be employed in the manufacture of motor-cars, industrial tools and firearms.

Nor is the manufacturer left entirely to his own unaided efforts. The Japanese Government is fully alive to the advantages of being independent of foreign supplies, and is assisting in a variety of ways in encouraging the establishment of new industries in the country. For example, to render Japan independent of German dyes and chemicals the Government is giving direct subsidies to factories making dyes and certain other chemical products. To encourage interest in the iron industry it has been decided to grant immunity from taxation of all descriptions for a period of ten years to persons undertaking the erection of iron foundries, and also to permit the importation

of the necessary ores and plant duty free. Other industries are assisted by granting drawbacks, when the products are exported, on some of the imported raw materials used in their manufacture, whilst by a system of shipping subsidies export trade in general is helped by ensuring that goods can be shipped to various markets at reasonable rates.

USE OF MOLYBDENUM IN ALLOY STEELS.

An investigation to ascertain why molybdenum as a possible source of economic wealth in the United States should remain undeveloped has been made by the United States Bureau of Mines, and a report on the facts obtained has been published. A preliminary review of the situation showed that the market for molybdenum in alloy steels must be developed or that new uses for the metal must be created before the demand would be sufficient to warrant any extensive mining of the ore.

One of the chief factors in retarding the development of any demand for molybdenum by the alloy-steel trade was that manufacturers who might use, or might investigate the possibilities of using, the metal were kept out of the market by the fear of not being able to obtain steady supplies. On the other hand, those who might be interested in the development of some of the extensive low-grade molybdenite or wulfenite deposits in the United States were prevented from doing so by the small visible demand and the fear that any large production would glut the market. Owing to these conditions, the mining of molybdenum has in the past been confined almost entirely to small-scale operations on high-grade streaks of molybdenite ore, and the methods of recovery have been limited largely to cobbing and hand-picking.

The problem before the Bureau of Mines was to ascertain the character and extent of the deposits of molybdenum ores in the United States from which supplies requisite for the development of the market might be obtained, and how the ores might best be concentrated into a marketable product. The direct purpose of the Bureau is, on the one hand, to prove to possible consumers of molybdenum that the element is not as rare as commonly supposed, and that the United States possesses many deposits of low-grade ore from which large supplies may be derived; and, on the other hand, to prove to present and prospective producers of molybdenum that there is a latent market for their product in the alloy-steel trade which needs only the assurance of steady supplies for a considerable development.

The new publication is Bulletin III., "Molybdenum, its Ores and their Concentration, with a Discussion of Markets, Prices and Uses." Copies may be obtained at 1*s.* 3*d.* each (exclusive of postage) by applying to the Superintendent of Documents, Government Printing Office, Washington, D.C.

A NEW ARGENTINE DYE MATERIAL.

According to a report by the United States Consul-General at Buenos Aires, a joint-stock company has been formed in Argentina for the exploitation of a new dye material "algarrobin," obtained from the wood of the carob tree (*Ceratonia siliqua*), and a factory has been established in the city of Santa Fé, Province of Santa Fé. The material is now in regular industrial use and is said to be giving good results, in addition to proving itself economical in comparison with other dye materials. One local concern, the Sociedad Italo-Americano, is said to be using 3,307 to 4,409 lb. of "algarrobin" monthly, chiefly in dyeing khaki cloth for Argentine military uniforms. It is also said that 66,139 lb. of the product have been shipped to Italy and France, and that additional requests are being received in consequence of the satisfactory and economical results given by the dye. The manufacturers claim that, although cotton takes the "algarrobin" successfully, exceptionally good results are obtained in the treatment of silk and wool.

"Algarrobin" possesses valuable dyeing properties. The fastness of the dye to fulling, light, washing, etc., is notable, as is also the uniformity of tone. These qualities, added to its moderate cost, will render it of value to dyers. "Algarrobin," alone, imparts a light-brown colour to any textile fibre—cotton, wool, silk, etc. These colours are fixed by appropriate mordants according to the shades desired. There is a great variety of methods of employing the dyestuff, and it will be easy for a dyer, with a little practice, to obtain all the tints he requires. In combination with vegetable extracts, such as fustic, hypernic, logwood, etc., it gives a number of varied and fast colours. It is very suitable as a base for dyeing with coal-tar colours, and by its use an economy of 50 to 90 per cent. of the artificial colours employed can be attained.

For the loading of silk and wool it is superior to all materials now currently used, both in regard to increase in weight and to the mechanical properties of the dyed wares.

GENERAL NOTES.

Anopheline Mosquitoes.—In connection with possible risks of malaria being acquired in this country, the Local Government Board are anxious to collect as much information as possible regarding the prevalence and distribution of anopheline mosquitoes in various parts of the country. Naturalists and field entomologists could give much valuable help in the matter by keeping notes and records of any adult insects which they may meet with during natural history searches, etc., and also of the detection of anopheline larvæ,

In making records the following are important: *Adults.*—Date; hour of collection; place (if in a building specify its nature); condition of weather and temperature; whether few or abundant. *Larvæ.*—Date; hour of collection; locality; nature of collection of water (natural or artificial); nature of breeding-place (shady pools, open collections of water, presence or absence of weed, fish, etc.).

ADULTERATED TEA.—In order to ensure that only genuine tea shall pass into the country, all consignments are examined at the ports of entry by inspectors approved by the Lords of the Treasury. Doubtful samples requiring a more complete examination are sent to the Government laboratory. The number of such samples dealt with in the year ended March 31st, 1917, was 13,296, of which 1,172, representing 65,511 lb., were condemned as containing sand or other foreign matter. In addition, 488 samples, or 34,666 lb., were reported as "unfit for human consumption." There was, however, the Government chemist points out, no evidence of intentional adulteration, and it is to be noted that the quantity rejected, though large, is quite insignificant in relation to the total amount of tea imported, namely, approximately 369,000,000 lb., including tea for the manufacture of caffeine. Rejected tea is allowed delivery duty-free for use in the manufacture of caffeine or theine, the alkaloid which imparts to coffee and tea their stimulating properties, and which is extracted for use as a drug.

COFFEE IN BRITISH GUIANA.—According to the *Journal of the Board of Agriculture, British Guiana*, the coffee industry of the colony continues to increase. In 1905 the area under cultivation was 1,432 acres; in 1910, 2,546 acres; and in 1915, 4,468 acres. The Liberian variety is chiefly planted, as it gives good returns, and costs less to cultivate than the Arabian variety. Most of the coffee produced in the colony is consumed locally, only a small proportion being exported.

WOODLAND INDUSTRIES.—The Forestry Sub-committee of the Reconstruction Committee, in their recent report, state that the wood distillation industry had failed to develop in Great Britain before the war, not because the raw material was not available or too expensive, but because of unscientific methods and lack of encouragement from the Government, which preferred to rely on Germany, Austria, and the United States. As illustrating their contention that no woody material should go to waste in a highly industrial country like this, the sub-committee refer to what has been accomplished by the utilisation of the produce of some 2,000 acres of coppice in the Crown woods at Tintern. Attention is also called, in the report, to other small industries, including tent-peg and spoke making, that have been set on foot during the war. The sub-committee add that, with the expenditure of a small amount of capital on better machinery, various other products—wood-wool, for example—might be turned out. Industries similar in character to those mentioned have been developed in other parts of the country. Home-grown beech and birch are quite extensively used in Scotland and in Lancashire for the manufacture of bobbins, thus reducing, to some extent, the import of birch bobbin squares from Northern Europe, while in the South of England hurdles are also made from underwood. Further examples of the uses to which coppice material may be put are clogs, chestnut-fencing, piano-keys, crate-making, ship-fenders, and pencils.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m.:—

APRIL 10.—W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association, "Examples of Applied Science in the Cotton Industry." PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., will preside.

APRIL 17.—FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." SIR JOHN SNELL, M.Inst.C.E., will preside.

APRIL 24.—MAJOR SIR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons." The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View."

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoons, at 4.30 p.m.:—

APRIL 18.—ALFRED DICKINSON, M.Inst.C.E., "Water Power in India." The RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., will preside.

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912-17, "British Guiana." SIR EVERARD IM THURN, K.C.M.G., C.B., will preside.

CANTOR LECTURES.

Monday afternoons, at 4.30 p.m. :—

J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day."

Syllabus.

LECTURE I.—APRIL 8.—Explosion and detonation—High and low explosives—Propellant power and disruptive violence—Requirements for military use—Materials and their sources—Ammonium nitrate and other nitrate mixtures and their military applications.

LECTURE II.—APRIL 15.—Other high-explosive mixtures and their uses — Chlorate mixtures — Nitro-cellulose and nitro-glycerine, and mixtures containing them—Military smokeless powders.

LECTURE III.—APRIL 22.—High explosives used for shell filling—Methods of detonation—Initiators of detonation — Tests applied to explosives — Miscellaneous.

SPECIAL LECTURES.

A special course of three lectures on "The Freedom of the Sea" will be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m. The first lecture will be given by Mr. GERARD FIENNES, the second by SIR FRANCIS TAYLOR PIGGOTT, LL.M., and the third by Mr. JOHN LEYLAND.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 8 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. J. Young, "Military Explosives of To-day." (Lecture I.)

Farmers' Club, 2, Whitehall-court, S.W., 4 p.m. Mr. T. B. Ponsonby, "The Standardisation of Agricultural Labour."

Brewing, Institute of (London Section), Imperial Hotel, Russell-square, W.C., 6 p.m. Mr. E. Earle, "The Application of National War Bond Schemes to Brewery Customers."

Surveyors' Institution, 12, Great George-street, S.W., 5 p.m.

Geographical Society, Burlington-gardens, W., 8.30 p.m. Captain J. S. Barnes, "The Future of the Albanian State."

East India Association, 3, Victoria-street, S.W., 3.30 p.m. Mr. K. M. Panikkar, "Problems of National Education in India."

TUESDAY, APRIL 9 ... Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Mr. D. Burns, "Democracy and Exceptional Ability."

Electrical Engineers, Institution of (Scottish Section), 207, Bath-street, Glasgow, 7.30 p.m. Mr. E. B. Wedmore, "The Control of Large Amounts of Power."

Asiatic Society, 22, Albemarle-street, W., 4 p.m. Dr. S. Langdon, "The Babylonian Conception of the Logos."

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. Joly, "Scientific Signalling and Safety at Sea." (Lecture I.)

Alpine Club, Savile-row, W., 8.30 p.m.

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Mr. E. Sandeman, "The Derwent Valley Waterworks."

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Dr. G. A. Boulenger, "Exhibition of a head of the Charasinid Fish, *Hydrocyon goliath*." 2. Miss J. B. Procter, "On the Variation of the Pit-Viper, *Lachesis atrox*."

Röntgen Society, Burlington House, W., 8 p.m. Professor Sir Ernest Rutherford, "Silvanus Thompson Memorial Lecture."

WEDNESDAY, APRIL 10 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Dr. W. L. Balls, "The Application of Research to the Cotton Industry."

Automobile Engineers, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 7.30 p.m. Captain H. Philpot, "Some Experiments with Notched Bars."

Colonial Institute, Caxton Hall, Westminster, S.W., 8.30 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Professor J. Joly, "Scientific Signalling and Safety at Sea." (Lecture II.)

THURSDAY, APRIL 11 ... Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Lieut.-Colonel C. S. Myers, "Experimental Psychology." (Lecture I.)

Electrical Engineers, Institution of, and Electrical Section of the Royal Society of Medicine. Joint meeting at the Cancer Hospital, Fulham-road, S.W., 7.30 p.m. 1. Dr. E. P. Cumberbatch, "Diathermy: the use of Electricity for heating the tissues of the body in disease." 2. Dr. R. Knox, "Single Flash (Instantaneous) Radiography, its possibilities and limitations." 3. Exhibition of electro-medical apparatus.

Historical Society, 22, Russell-square, W.C., 5 p.m. Miss V. Methley, "The Ceylon Expedition of 1803."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. A. H. Scott, "Concrete Ships."

Mining and Metallurgy, Institution of, at the Geological Society, Burlington House, W., 5.30 p.m. Presidential Address by Mr. H. F. Marriott.

FRIDAY, APRIL 12 ... Royal Institution Albemarle-street, W., 5.30 p.m. Professor E. C. C. Baly, "Absorption and Phosphorescence."

Astronomical Society, Burlington House, 5 p.m.

SATURDAY, APRIL 13 ... Royal Institution, Albemarle-street, W., 3 p.m. Professor E. H. Barton, "Musical Instruments Scientifically Considered." (Lecture I.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—April 5, 1918.

No. 3412. APRIL 12, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

Royal Society for the Encouragement of Arts, Manufactures and Commerce.

The Royal Society of Arts was founded in 1754, and incorporated by Royal Charter in 1847, for the Encouragement of the Arts, Manufactures, and Commerce of the country.

At present the Society numbers about three thousand Fellows. The annual subscription is Two Guineas, the life subscription Twenty Guineas. There is no entrance fee.

Fellows are entitled to be present at all the meetings of the Society. These include the Ordinary Meetings, held every Wednesday during the Session, when papers on subjects relating to inventions, improvements, discoveries, and other matters connected with the Arts, Manufactures, and Commerce of the country are read and discussed; the Meetings of the Indian and Colonial Sections, at which subjects connected with our Indian Empire and the Colonies and dependencies are considered; and the various lectures on technical subjects delivered under the Cantor and other trusts. Fellows also receive a weekly copy of the *Journal*, which contains full reports of the Society's proceedings, as well as a variety of information connected with Arts, Manufactures, and Commerce; and they are entitled to the use of the library and reading-room, and to attend the Conversazioni.

Proposal forms, and further particulars relating to the work of the Society, may be obtained from the Secretary, Mr. G. K. Menzies, at the Society's House, John Street, Adelphi, London, W.C. (2).

Journal of the Royal Society of Arts.

No. 3,412. VOL. LXVI.

FRIDAY, APRIL 12, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, APRIL 15th, at 4.30 p.m. (Cantor Lecture.) J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." (Lecture II.)

WEDNESDAY, APRIL 17th, at 4.30 p.m. (Ordinary Meeting.) FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." DR. J. A. VOELCKER will preside.

THURSDAY, APRIL 18th, at 4.30 p.m. (Indian Section.) ALFRED DICKINSON, M.Inst.C.E., "Water Power in India." The RIGHT HON. LORD LAMINGTON, G.C.M.G., C.C.I.E., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, April 8th; MAJOR-GENERAL SIR DESMOND D. T. O'CALLAGHAN, R.A., K.C.V.O., in the chair. Mr. J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, delivered the first lecture of his course on "Military Explosives of To-day."

The lectures will be published in the *Journal* during the summer recess.

SIXTEENTH ORDINARY MEETING.

Wednesday afternoon, April 10th; PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., in the chair. A paper on "Some Instances of Applied Science in the Cotton Trade" was read by Mr. W. LAWRENCE BALLS, Sc.D., Manager of Cotton Investigations for the Fine Cotton Spinners' and Doublers' Association.

The paper and discussion will be published in the *Journal* of May 3rd.

PROCEEDINGS OF THE SOCIETY.

FOURTEENTH ORDINARY MEETING.

Wednesday, March 13th, 1918; HIS GRACE THE ARCHBISHOP OF CANTERBURY in the chair

The following candidates were proposed for election as Fellows of the Society:—

Aiyar, K. V. Venkataramana, Madras, India.
Besant, A. Digby, London.
Boyd, John T. M., New Zealand.
Butson, Cecil W., Hankow, China.
Hosain, Dr. S. A., Mambuw, Federated Malay States.
Jackson, Right Hon. Frederick Huth, M.A., London.
Meling, Einar, Norway.
Muntz, Sir Gerard Albert, Bt., Stratford-on-Avon.
Narasimham, G., Madras, India.
Preston, Arthur Phillips, Teddington.
Rae, William, M.Inst.M., Kinlochleven, Argyllshire.
Simkins, Alfred George, London.
Spencer, Samuel, Assoc.Inst.C.E., London.
Stephens, Albert John, Gloucester.
Webb, Herbert Charles, London.
Wilson, Edmund Richardson, L.R.I.B.A., New Zealand.

The following candidates were balloted for and duly elected Fellows of the Society:—

Alley, Stephen Evans, J.P., M.I.Mech.E., Shrewsbury.
Briggs, Francis Henry, Knighton.
Chatfield, William Charles, New Zealand.
Davey, Hon. Arthur, J.P., Godalming.
Hart, Sidney George, London.
Leetham, Sidney, York.
McArthur, Thomas, Liverpool.
Reid-Hyde, Major James, London.
Rogers, Henry, Birmingham.
Smith, Alfred, Keighley.
Stewart, Murray, London.
Turner, Sir Montagu Cornish, Romford.
Woodthorpe, John Brinkler, F.C.A., Vancouver, British Columbia.

The Chairman, in introducing the author of the paper, said he desired to be the spokesman for everyone present, and for many who were not present, in welcoming one who had come to describe, from first-hand knowledge, and with authority beyond dispute, the past and the present of a city which had long had an interest—industrial, artistic, and religious—in the life of Europe, and which had now for all English people a very deep modern interest, and for some of them an interest of a very sacred character indeed. The author was going to describe one of the supreme tragedies of the world war, the destruction of what had been beautiful in itself and of great historical interest—a destruction of a kind to which the world had hardly seen a parallel. It was well to collect one's thoughts on an occasion such as the present and put the facts of the war before one's mind in their true setting, as a reminder that the Allies were fighting for the elementary principles of civilisation. Such a meeting as the present one should stimulate the deep sympathy, the active interest, and the warm support of everyone present for all that concerned the welfare of the gallant country of which Ypres was one of the great ornaments. He thought there might be others in the room besides himself who felt somewhat ashamed of the fact that, although journeying often on the Continent, they had failed during past years to become acquainted with a town of such beauty and so many interests, historical and others, and an architecture of a kind which outside Italy had been rare in its combination of municipal, civic, and other glories. Personally he had never seen Ypres in its glory. It was his privilege to spend a day there less than two years ago, but it was not in its glory then; he only saw the shattered ruins of a place which retained then—to a greater extent than at the present time, he feared—at least some traces of what its glories had been. He saw it under conditions of extraordinary difficulty, amid the shriek of shells and the groan of aeroplanes, clad in the unwonted garb of gas mask and helmet, and under circumstances which made quiet thought about what it all meant very difficult. That quiet thought had since had time to mature into the deepest and keenest interest and the greatest anxiety to know all that was to be known about a place which, both in its past and in its present, had so large a claim upon the interest of everyone in this country. It was no small privilege to listen to a paper by a man who was perhaps better entitled than anyone to speak about what Ypres formerly was and what it was to-day, to compare the one with the other, and to put forward also, it was to be hoped, some suggestion of what it might yet revive to become in the future.

The paper read was—

YPRES AND OTHER FLEMISH CITIES BEFORE AND SINCE THE WAR.

By Paul Lambotte,
Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique.

The systematic destruction of the monuments at Ypres by the German army can by no means be justified by any strategic necessity. It is another proof of that Germanic state of mind which makes war, not only against men, but against ideas.

The first startling manifestation of this barbarian mind was the destruction and sack of Louvain. The second was the bombardment of the Cathedral of Rheims. In the determined ferocity displayed towards the Belfry and Cloth Hall of Ypres, we can scarcely doubt that we have a third.

Louvain is the centre of culture and diffusion of catholic science. The University of Louvain, the *Alma Mater*, is essentially the spiritual citadel of science in harmony with faith. It is against her that this crime, coldly premeditated and carried out, was intended. The burning and pillage of the celebrated library, and the devastation of the Cathedral, proclaim this clearly.

The persecutions and fusillades of which so many prelates, monks and priests were the victims in Belgium, and the bombardment of the Cathedral of Malines, were caused by the same spirit, by the same sectarian hate of the Lutheran Emperor who, like a spoilt child, thinks he can annihilate a tradition or a doctrine by throwing down the edifice which it has inspired.

Rheims is, in a way, the Palladium of France's history, creed and tradition. Germany wished to abolish it. It is the glorious symbol of a wonderful national history, which the invading army struck at and tried to destroy. The attempt made on the cottage and chapel of Joan of Arc at Domrémy was inspired by the same mania.

Ypres, on the other hand, is the striking symbol of the persistence of the spirit of the old communers, of the survival of that local particularism which, since the earliest Middle Ages, put the town-halls of Belgium in opposition to the palace of the suzerain or his deputy.

The autocrat, steeped in the principles of Prussian militarism, imbued with the prejudices engendered by the narrow discipline of an army spread over the whole nation, could not fail to attack a monument which stood for a type in itself.

In the centre of this dead town, with its imposing dimensions and sumptuousness, it stood as an irrefutable witness to the victories all down the ages of the commune burghers and the guilds of artisans over the central power represented by the suzerain or his vassal, by the monarch or his governor. The communal spirit survived feudalism and all the following *régimes*, and still retains its tenacious influence in Belgium.

The Belfry and "Halles" of Ypres were bombarded and burnt by order of the same despotic and brutal will that determined the arrest and imprisonment of Burgomaster Max. These buildings typify the materialisation, and this man the incarnation of the same bold spirit of local resistance which the imperialism of a William II. could not tolerate on the path where he threw his servile hordes.

Such, then, is the meaning of this act of vandalism, which has once again impoverished the whole world by taking away one of its most significant *chefs-d'œuvre.*

Ypres, that magnificent town, has never been so much talked about as since she no longer exists. It is often thus with men, whose death brings them before the public, and whose celebrity is all posthumous. Up to that moment only the initiated knew the value of their mind or of their deeds, but circumstances never drew public attention to them. In the same way, Ypres had her group of devotees, but these were not very numerous and did not devote much literature to her monuments or her memories. Foreigners all knew Bruges, the Venice of the North—Bruges la Morte—who was only asleep.

Bruges was on the programme of every well-arranged trip to Belgium, but Ypres was far off and had less obvious charms. It was difficult to get to, trains did not fit in, there were many changes and much loss of time. The best way to go was by motor from Ostend, or one of the seaside resorts of the Flemish coast. And doubtless this was often done. It was a regular excursion for bathers. But they got there for lunch, and as they always wanted to be back at the sea for tea, the visit to Ypres was rather cursory. They were satisfied to drive through the Grand' Place, telling the chauffeur to go slowly. They did not go into any of the buildings, passed the Belfry and Cloth Hall, glanced sometimes at the Cathedral standing in the corner of the square, and, when leaving the town, admired the moat and the ruins of the old ramparts just as the car was gaining speed.

I need not say that this was not the way to visit this unique town, whose civic monuments were the grandest of any that the past had left us. Ypres was a drowsy town, a city of dreams and nostalgia. The number of its inhabitants during the last century was out of all proportion to its size. It had no longer any industries, and only the lace-makers in the doorways, shuffling the bobbins on their pillows, showed any activity in the dreary lassitude of their surroundings.

The Belgian Government had founded a school for cavalry officers at Ypres. The young men going through their course there brought a little noise and gaiety with them. In the summer, the owners of the country houses round came in on market days and also on Sunday morning to attend mass. Then there were motors, carriages, pretty frocks, meetings and gossip; for the country round Ypres was studded with country houses, villas and chateaux. Many rich Frenchmen had bought estates, farms or land there. They thought it safer to put their money into Belgian land, because they were alarmed by the threatened income tax and socialistic tendencies of the French Government. Alas! if they had known!

Since the beginning of the war, first the Belgians, then the French, but later chiefly the British, have defended Ypres, and this terrible salient of the Western front has cost the Allies innumerable young and precious lives. The German has never trodden the sacred soil of Ypres, but as the town was within range of his guns he destroyed it furiously, and practically has not left there one stone upon another.

There is also no doubt that the rancour and fury of the Kaiser and the German staff were partly the cause of this vindictive destruction. For, do not let us forget, the Belgian army had, for the third time since the commencement of the war, just prevented the realisation of the Emperor's plans.

The first time was at Liége when, under General Leman, they held up the invader for ten days. The second, at Hofstade, September 9th, 10th, 11th and 12th, when they obliged two army corps, which were marching on the Marne, to turn back. Without this diversion these troops might very probably have turned the tide of this decisive battle. The Germans recognised it, excusing themselves for not having foreseen such a possibility.

Dr. E. Jaeger, one of the most authoritative members of the Reichstag, wrote in the *Allegemeine Rundschau:* "If the Belgians had not stopped and held us by their obstinate

defence, we might have put at least five army corps more on the Marne, we should have won the battle and entered Paris. It was the resistance of the Belgians which prevented us from taking Paris and winning the war."

The third time was on the Yser. The Belgian army, exhausted by seventy-five days of campaign in which they had struggled alone, absolutely alone, against the German armies on the march to Paris and Calais, still heroically held on for ten days, helped by 6,000 French marines, against the shock of all the German forces and the full blaze of their artillery. This respite gave the French and British time to act. Calais was saved, but Ypres paid for this check.

At Ypres there was not only the Cloth Hall, the Belfry and the Cathedral of St. Martin, which have been so much talked of during the last three years; but those who knew Ypres, or had lived in its neighbourhood, know that in all the squares, streets, and even in the shadows of its alleys, were to be found houses and monuments dating from every period.

With the Belfry and "Halles" and Cathedral of Ypres, it is not only architecture that disappears. Buildings in their general structure can be restored. Their survival is only assured by repeated restoration. It is art, precious memories and history which sink and die.

Yes, history was written by painters on the walls, by sculptors in the stone or tombs and statues, by artisans in a thousand forms. The physiognomy and the soul of the old city are brutally demolished. Such losses, like those of the manuscripts and priceless books at Louvain, like the sculptures of the façade of Rheims, nothing can repair. They are final.

Before the war the lethargic town of Ypres spread over the low plain of Flanders, her towers and gables dominating the remains of her old ramparts, dismantled in 1856. She smiled on her reflection in the canals and ponds fed by the sluggish stream of Yperlée.

Gradually reduced since the twelfth century from a population of two hundred thousand souls to a number which did not reach twenty thousand, she still displayed everywhere the traces of her ancient splendour and her long prosperity. Like an ancestress, she drew a touching prestige from the inactive but wonderful charm of the past.

Ypres, in the course of the ages, had often been besieged. It was invested by the English in 1383, taken by the mercenaries of the Prince of Parma in 1584, taken and retaken by the French in the seventeenth century, and later by the armies of the Republic and the Empire; but Ypres never knew such barbarism and horror as that which, during these last four years, has ruined her for ever.

"Kultur" only could destroy so much beauty and so much art. As a fortified town, Ypres, throughout the centuries, had been spared. As an open town she was burnt and crushed, even to her museums and most precious monuments of the past.

Long ago the fullers and wool merchants of Ypres kept four thousand looms at work. It was at the expense of their corporation that the gigantic Cloth Hall was erected, which took more than a century to build.

The eloquence of the past was so persuasive at Ypres. The Grand' Place, wide and long as for a great population, the giant Belfry, the enormous halls, the immense Cathedral, appealed to the least sensitive imagination. And the old houses, once so sumptuous, proclaimed the evolution of styles in the art of building, from the façade of the Rue de Lille, the Boucherie Gothique and the antique "Gasthuis Belle," to the dwellings dating from the reigns of Louis XV. and Louis XVI., all telling how local life persisted and still flourished through so many vicissitudes. Nothing remains now of all these treasures.

I am going to show you quickly on the screen the progressive destruction of the monuments, the irremediable damage done.

Here is the Cloth Hall with the Belfry, those marvels of which a French author has written: "This monument, by its proportions, recalled the majesty of the cathedrals, by the beauty of its architecture the Venetian palaces, by the elaborated sumptuosity of its ornaments the buildings erected by the Spanish Moors." Here is a fragment of the "façade," showing the trefoils in the pointed arches of the "Halles" (Cloth Hall).

Now look at what the Hun did. This photograph was taken in December 1914. It shows a first state of destruction. Another striking picture, showing a view taken from a spot in the neighbourhood of the Museum, December 1914. Now we see the Cloth Hall and Belfry as they stood at the end of December 1916. The ruins were most impressive. This shows the frontage of the halls—the photograph was taken the same day as the former one. A picture of the *salle voutée*, April 1917 (there, in old days, was held the market). And this is the *ensemble* of the ruins as they stood in

June 1917, and they are still nearly in the same state to-day.

I told you that history had been written by our painters on the wall.

The present picture shows the interior of one of the painted galleries. Some frescoes dated from the fourteenth and fifteenth centuries. They had been rashly restored. The others had been executed during last century.

Guffens, Swerts, Pauwels, and the more majestic Delbeke, had portrayed there the great events of the town's history. Delbeke, in his frescoes at Ypres, had shown to the fullest extent an individual and curious talent. Nowhere else is there any really important work of his. He died relatively young, leaving this expressive series almost finished. Now there is nothing left of Delbeke's works, except a few sketches and unimportant little pictures. This painter, who was worthy of a high place in the modern Belgian school, has passed for ever into nothingness. When we think of the enormous interest taken in the smallest fragments of frescoes nowadays, we can well imagine the admiration which would have been expended in the future on this harmonious collection now so ruthlessly destroyed.

This is a view of the curious and little known "Gasthuis Belle" (almshouse, hostel). It was founded in the middle of the thirteenth century by Salomon Belle, Seigneur de Boesinghe, and his wife Christine de Guines. The family of the "Seigneurs de Boesinghe" is not extinguished nowadays.

The "hospice Belle," among numerous antiques and curiosities, possessed a very precious triptych by Melchior Broederlam, Court painter to Philip the Bold, Duke of Burgundy, from about 1382 to 1401. This work of the predecessor of the Van Eycks is a document of the highest interest painted by the old Ypres ancestor of the Bruges school. With charming simplicity, though already using good technical means, he has painted the Virgin and Child between the donors accompanied by their patron saints.

The Virgin Queen, sweet and dainty, crowned with gold, is dressed in red and gold brocade. Yolande Belle, granddaughter of the founders, and her husband Jean Bride, the donors, surrounded by their sons and daughters, are painted on the wings. Jean Bride is accompanied by St. George, in bizarre armour, Yolande by St. Catherine. They have dwelt in the hostel since the fourteenth century throughout all other wars and vicissitudes.

My learned friend, Baron Kervyn de Lettenhove, showed the old triptych at the first of the three celebrated exhibitions of Old Masters he organised in Belgium, the "Primitifs Flamands" and "La toison d'or" at Bruges, Belgian art of the seventeenth century at Brussels. These three exhibitions drew a large crowd of foreign visitors, and even the German Emperor, his Empress and their only daughter, came to see the wonderful art treasures filling the third. The Kaiser was amongst the exhibitors; he had lent pictures savagely restored—I mean ruined—by German professors.

He probably made a note of what he intended to loot later on in Belgium; but that day, although he seemed frightfully anxious about a possible attempt on his life, and ordered the public to be carefully selected and drastically kept far from him, he spoke to us only of art and peaceful prospects.

The triptych by Broederlam, I am glad to say, has not been destroyed with the hostel. That most rare and invaluable masterpiece, prior to the discovery of oil painting, was removed when only slightly injured by the bursting of a distant German shell. It is now kept in Paris, with a great number of other relics saved from the part of Belgium which is under range of the German guns.

The Belgian Minister for Science and Art had early in the war taken steps to transfer in safety all valuable things that could possibly be removed. The "Mission du Ministère des Sciences et des Arts" has done marvels, and even under the bombardment our agents have saved invaluable treasures. It is only a small part compared with what Belgium has for ever lost.

The director of the mission, the well-known architect Eugène Dhuicque, is responsible for the greatest part of the photographs I show to-day. I am glad to express here my gratitude for his help. Others are lent to me by M. Butaye, who used to live at Ypres and cherished his town with filial feelings. But let us come back to the monuments.

After the Cloth Hall with the Belfry, I will show you the Cathedral of St. Martin, which was a huge and splendid Gothic church. The interior was crowded with memorials. Among those I quote, just for a memento, the flowery Gothic monument erected to the memory of Louise de Laye, widow of Hugonet, Chancellor of Burgundy, and the tomb of Antoine de Henin, and the stone covering the remains of Jansénius, Bishop of Ypres, the austere founder of Jansenism.

The magnificent rose-window is in atoms, and the triumphal arch constructed in 1600 by Urban Taillebert, overthrown. And the rood-screen with alabaster statuettes, the pulpit so exuberantly sculptured, the choir-stalls—a model of woodcarving—and the painted vaulting are all burnt up.

I next show views of the nave and the steeple in 1915; interior of the choir, 1915; the transept, north side, 1915; another sight of the steeple (it is the western side), 1915; view of the exterior and steeple in 1916; interior of the Cathedral, 1916; last sight of the steeple in 1917. Finally the steeple collapsed in 1917, on Good Friday, at eight o'clock in the morning. The Boche can be proud of his deeds.

Now I am going to evoke a few of the odd and charming old corners that made Ypres so fascinating. This is the "Ancienne hall à la Boucherie," a very old and picturesque building, used as a museum. It is the oldest church of Ypres—older than the Cathedral of St. Martin—St. Peter's (a Norman building, the "Portal" dating from the eleventh century). Interior—at the bottom are the remains of a huge altar of the seventeenth century. This belongs to the sixteenth century, "L'ancien Béguinage."

You know the silent and lovely Flemish béguinages—those of Bruges, Ghent, Dixmude, Lierre, and so many others have been so frequently reproduced by the artists. They were peaceful, like anterooms of heaven.

A shop, Rue de Dixmude: an old and quaint shop of which you can see a picture in the book by Henri Hymans "Bruges et Ypres," in the series published at Paris under the title "Les villes d'art célèbres."

Now the seventeenth century at Ypres. The *nieuw werk*—it means the new work; you see how Flemish and English are sometimes related. It was built on one side of the Cloth Hall. School of St. Francis, Rue de Dixmude: a picturesque frontage. This is the same after the Mission du Ministère des Sciences et des Arts had removed every stone of this frontage whose destruction was certain. The stones are numbered, and it will be possible to reconstruct later on the building exactly as it stood. The lovely statue of the Virgin (carved in wood) has been saved.

Now we come to the eighteenth century, which had dowered Ypres with numerous lovely houses. The Musée Merghelynck. The Hotel Colaert: these are the remains of the outhouses. It is in the same style as the beautiful Hotel Merghelynck, of which nothing remains. The town house of Chevalier Hynderickx, Rue des Chiens The gate of the same: British soldiers on the threshold.

Even the nineteenth century had left a few nice buildings in Ypres. I am sorry I cannot show you—the slide has been broken—a lovely pavilion constructed by the painter Delbeke, the man who painted on the Cloth Hall walls, at the bottom of his garden, overlooking the River Yperlée. The ruin is a charming picture.

"La Visite de la Reine." Those are slides showing Her Majesty, the Queen of the Belgians, amongst the ruins of the unfortunate town. And so, you see, Ypres is no more.

You have seen all that is left of the famous square at Ypres, of which Michelet, in his book "On the Roads of Europe," wrote so justly:—

"The Grand' Place of Ypres, though for other reasons and under more austere skies, is worthy of being as precious to mankind, as sacred, and as intangible as the Piazza San Marco in Venice, the Piazza della Signoria in Florence, or the Cathedral Square of Pisa. It is a unique and irreproachable monument of art."

And see what the Germans have made of this spot, so precious, sacred and intangible. Are they not also now trying to destroy Venice?

As my compatriot Jean Dardenne writes: "Those who systematically destroyed the Grand' Place of Ypres, and those who approved of its destruction, have morally ceased to belong to the human race, they have descended the scale of being to a rung somewhere between savage beasts and asses. . . . Emperor William will share with Nero the glorious infamy of having premeditated and committed such execrable crimes against civilisation."

Alas! Ypres, sad martyr, your casket of buildings has lost the dear old cloister with its flamboyant arches; the quaint "conciergerie" built in the seventeenth century in Renaissance style, which everywhere else was out of fashion; the charming "sister's workrooms" at the hospice St. Jean; the gabled façades of the old Abbey of Thérouanne; the tower of St. Nicholas; the Hotel Merghelynck, enclosing a museum of the eighteenth century, furniture and ornaments; and the churches and ancient city gates, and the old houses—all these touching and picturesque relics of the past.

Even if there shall be anything left among the ruins and *débris*, the wounds and outrages inflicted by the enemy on our ancestor city can never be effaced. Art, history, tradition, and legends have flourished there, and are abolished.

The crime of those who willed this annihilation can find no excuse.

Ypres was the largest, the most precious and beautiful of the Flemish cities crushed by the Hun. Many others also—towns or villages—had kept the remains of old prosperity and artistic splendour. All those villages whose unknown names suddenly became famous by the terrific battles raging there—Pervyse, Reninghe, Ramscapelle, Steenstraete, Bixschoote, Het Sas, Elverdinghe, etc.—had huge Gothic churches, town-halls, and relics of the past worthy of universal admiration.

The heart of our old and dear Flanders was still alive in so many drowsy towns, under the shadow of their towers and their gigantic trees. Nieuport, Dixmude, Furnes, like Bruges and Ypres, were full of treasures. The two first are no more, the latter is still standing, wounded, partly blown up, so moving in her distress and agony.

We are now going to review quickly a few of their sights. First the villages.

This is Loo, which had a splendid old church and very good private houses that had stood for centuries. Church: a picture showing the hole caused by a shell in the wall of the apsis; the steeple is still untouched. The vestry. The church has suffered much. Interior of the nave. The steeple has been overthrown. This picture was taken immediately after the fall of twenty-seven bombs in the sanctuary. The German gunners had enjoyed a good time.

Woesten, a village five miles from Ypres. It has been defended by the Belgians, the French, the British, the French again, and the British once more. The shelling never ceases there. This is the church—another view of devastation.

Neuve-Église. Another beautiful church not far from Messines. It dated from the fifteenth and sixteenth centuries, and was burned in the first weeks of the war. It has been shelled without intermission since.

This is Dixmude. The ground where she stood is still in the hands of the Boche. She has been absolutely smashed. I can give only a few views of the past, just to show how picturesque she was and what we have lost.

A bridge over the Yser. This view has been painted and engraved a thousand times by our artists, as well as a spot not far distant called "La maison du juge." Dixmude had also a lovely béguinage, full of beautiful flowers smelling sweet in the summer sun, and much praised by our artists. What has become of the shy and timid nuns who were living so peacefully, far from the world and its vanities, in this delightful convent? This is the magnificent altarpiece by Jacques Jordaens, one of his masterpieces; it has been burnt to ashes. And this is the celebrated screen, immense, and carved as delicately as an old Chinese ivory or reliquary; it has been smashed to atoms.

This is Nieuport, a very old town too, near the mouth of the Yser. In her close neighbourhood was Nieuport-bains, a seaside resort. This is the old church which formerly, surrounded by large trees, was a beautiful picture of the past. Interior of the choir: two columns only are still standing. The old Calvary in the cemetery; graves of French soldiers; at the bottom the ruins of the church. The "Halles" and Belfry —what is left.

And this is Furnes. A view of the beautiful Grand' Place, town-hall, law courts, belfry A passage under the town-hall, 1915. View of an old Flemish town: the apple market; in the bottom the Church of St. Walburge, 1915; a house standing on the left side, still untouched; the same house destroyed at the corner of the apple market—a few days after.

Corner of the Grand' Place. Interior of the Church of St. Walburge: the splendid stalls carved in oak by Urbain Taillebert. They have been dismounted and removed by the Mission.

The Grand' Place again: King George, with King Albert and the Prince of Wales, watching the troops parading.

You have seen now a slight part of what Belgium has lost of her artistic and historic treasures. You will agree with me that when peace comes no money will repay such irremediable losses. The only way to restore, as much as is practically possible, our national inheritance, is to give back to our museums all the splendid works of art executed during the past centuries by our artists on our soil and which are now the principal features of the German and Austrian museums. We want to retrieve from the Kaiser Friedrich's museum at Berlin the wings of the celebrated altarpiece of Ghent, "The Adoration of the Lamb," painted by the brothers Van Eyck, in order to see, in its former state again in the Cathedral of Ghent, that wonderful masterpiece of the inventors of oil-painting. We want to retrieve from Vienna a few pictures by Peter Breughel the old, that thoroughly Flemish master, one of the most interesting artists of our school from the technical point of view, as well as by its popular humour. And from Vienna also the altarpiece painted by Rubens, for the Royal Church of St. Jacques sur Caudenberg in Brussels, a special commission

given to the artist by the Archduke Albert and his wife Isabella of Spain, who presented the picture to their parish chapel. And from Frankfort the panels of the Master of Flemalle, of capital importance for the history of old Flemish art, and from Munich, and from Dresden, and from Cassel, and from so many other places the principal pictures, statues, tapestries, wood-carvings, bits of furnitures—all created on our soil by our own artists and craftsmen.

Those things would be in the future--for us and for our foreign visitors—a slight compensation for the loss of our monuments and their contents.

Martyrised Belgium deserves to become a unique museum, and a pilgrimage for all the lovers of art.

I trust that the Allies, and specially the Belgian diplomatists, will not forget the point when discussing at last the peace terms with the hated Boche.

I am ready to supply them with a full list of paintings and works of art that we want only to complete the representations of our own glorious Old Masters in our national museums. All our British friends will come and admire them in Belgium, again free, and—let us hope—flourishing!

The Chairman (His Grace the Archbishop of Canterbury), in moving a hearty vote of thanks to the author for his clear and eloquent paper, said its interest was pathetic, and the sympathy it had inspired profound, and the indignation which underlay the feelings of those who had heard it was not easily restrained. The author had mentioned that the physiognomy of Ypres had been demolished, and he feared that was so, but the spirit remained of a city which had inspired the heroic resistance which had been displayed by Belgium against the ravages of the enemy, and it was to be hoped that that spirit would be seen again in the full exercise of ingenuity and forcefulness and progress in the days to come. He asked the author to accept not only the thanks of the meeting for his paper, but also an expression of their sympathy, their admiration, and their gratitude for the nation and people of Belgium, to whom this country owed so much.

Mr. Alan A. Campbell Swinton, F.R.S. (Chairman of the Council), seconded the motion, which was carried unanimously.

His Excellency the Belgian Minister said the presence in the chair of the Archbishop of Canterbury was an honour which he appreciated deeply, and he was sure that he could speak for all present when he offered his Grace their warmest thanks. He would like to say especially how much the Belgians present appreciated the honour; nothing could show better how the sufferings and the trials of the Belgian people were still the object of sympathy in England, and nothing could emphasise more strongly the high moral principle for which the Belgian cause stood in the war. It was not only at the present time that his Grace was interested in Belgians in England and in invaded Belgium, for he had given many proofs of his constant and active sympathy; but the presence that afternoon of the highest authority of the Church of England was of special significance. What had the author shown so clearly? The mutilation of the works of art designed to elevate the soul and help it to attain its ideal; the destruction of the riches of a past, with its memories of work, of tradition, of faith, and of prayer; the devastation of a peace-loving land, the seat of an ancient and high civilisation, where a hard-working and honest population hoped to fulfil their destiny, ruled by the noblest religious and æsthetic ambition. That destiny, which might be called a dream if it had not known centuries of reality, had been brutally and pitilessly brought by German aggression to a sad termination. But civilisation could never die, any more than right could be silenced or liberty oppressed for ever. In the ruins which had been shown there was a promise of resurrection. The monuments of Ypres had not been destroyed in vain; for the splendid deeds, of which Ypres had been the theatre, had erected a monument of heroism which no German shells could destroy. The sons of Great Britain and Belgium would come to Ypres as pilgrims, when right had been vindicated by the complete restoration of Belgium, to render thanks for the sacrifice of thousands of British heroes who died there for the cause of justice and civilisation. He offered the thanks of the meeting to his Grace for presiding, for the support of his high spiritual authority, and for the encouragement of his cordial sympathy.

The Chairman, in thanking the Belgian Minister for his remarks, said that the meeting might help to keep alive and stimulate just those thoughts to which His Excellency had given such eloquent expression. If those present went away from the meeting with such thoughts in their minds, they would feel that, sad as was the story to which they had listened, and the pictures which they had seen, even the destruction of so many beautiful monuments might not have been in vain if it meant the resurrection of something greater.

The meeting then terminated.

STEAM NAVIGATION ON THE UPPER YANGTZE.

Steam navigation on the Upper Yangtze—that is, above Ichang—is attracting much attention, and is proving very profitable to the operating companies. The Szechuan Steam Navigation Co., the oldest firm now operating steamers on

this section of the river, runs the steamers "Shu-tung" and "Shu-hun," both of which were built in Great Britain, and have proved that it is possible to navigate successfully the upper river. Another ship, the "Ta-chuan," owned by the Szechuan Railway Steam Navigation Co., has successfully completed its third year's service. For the journey of 400 miles between Ichang and Chungking the cost of sending freight is from about £3 10*s.* per ton upward, depending on the nature of the cargo. The cost of a first-class passage by the steamship "Shu-hun" is £8 for the up-river journey, and £4 for the down-river trip. The up-river journey takes from three and one-half days in the case of the "Shu-hun," to five or six in the case of the other ships. The down-river journey is made in two days, and passenger and freight rates are accordingly lower.

In July, 1916, the steamship "Lien-hua," belonging to the Teh Yu Steamship Co., which is registered in Hong-Kong, made its trial trip to Chungking. On this run certain machinery defects were developed which necessitated its return to Shanghai for alteration and repairs.

In October the "Chu-chuan," owned by the Szechuan Railway Steam Navigation Co., made its maiden trip to Chungking, accomplishing the journey in six days. This vessel is of the same type as the "Shu-hun" and is almost as large. It is 190 ft. over all, 30 ft. in breadth; draught, when loaded, 6 ft., and it has triple-expansion engines of an estimated horse-power of 1,000. The sister ship "Chi-chuan" is an exact counterpart of the "Chu-chuan."

Two ships, "I-chiang" and "I-chou" have been constructed at Shanghai for the Wanhsien Shang Pau Min Chiang Steamship, Co., Ltd. These steamers are said to be about 130 ft. long. Besides these ships, the Standard Oil Co., of New York, and the Asiatic Petroleum Co. have each one ship under construction at Shanghai. These ships, in all probability, will be devoted solely to the transportation of the products of the owners.

In 1916 the three steamers, "Shu-tung," "Shu-hun," and "Ta-chuan" did not resume their services until July, and later in the case of the "Ta-chuan." This delay was due to political conditions. In 1917 the steam navigation season was expected to open with eight steamers on the Ichang-Chungking run, in addition to the vessels of the oil companies. Still further expansion is probable.

A steamer service between Chungking and Suifu has been maintained since the middle of 1916 by the "Jui-yue," a small boat. During high water this vessel went as far as Chia-ting Fu, on the Min River, about 300 miles west of Chungking. The "Yuan-chi," another small steamer, has arrived from down river for service above Chungking. Two other vessels, the "Ching-yue" and "Ching-an," which had been operated in certain seasons both below and above Chungking, have been condemned by the Customs authorities, and probably will not again be seen on the upper river. Vessels plying above Chungking are operated under the Inland Waters Navigation rules.

The next few years, writes the United States Consul at Chungking, will undoubtedly witness considerable expansion in steam navigation above Ichang. It is expected that competition will reduce freight rates somewhat, but so long as navigation is attended with a considerable amount of risk, rates will remain relatively high. There are certain conservancy schemes under contemplation for the improvement of navigation. Were a sufficient sum of money made available for conservancy work, undertaken under the direction of expert foreign engineers, the navigation facilities of this section of the river could be greatly improved, and probably made possible for twelve months in the year.

COFFEE EXPORTATION FROM COSTA RICA.

According to an official publication, the total exportation of coffee from Costa Rica during the season August, 1915, to April, 1916, was 37,134,182 lb. gross, or 33,853,707 lb. net, of which 66·34 per cent. was fully treated, and 33·66 per cent. was with the parchment covering. The coffee shipped "in parchment" has had the fermentation and the drying processes, but no other: it is called "pergamino," while that fully machined is called "beneficiado." In calculating the net weight, a reduction of 18 per cent. is made for the parchment-covered coffee, and there is also an allowance for tare. How this quantity compares with exports in preceding seasons the following table discloses:—

Season.	Pergamino.	Beneficiado.	Total.
	lb.	lb.	lb.
1906-7	21,639,978	16,556,275	38,196,253
1907-8	12,392,989	7,399,076	19,792,065
1908-9	12,050,261	14,471,575	26,521,836
1909-10	18,397,415	13,342,370	31,739,785
1910-11	17,086,045	10,782,929	27,868,974
1911-12	13,036,539	13,943,354	26,979,893
1912-13	10,774,461	17,927,647	28,702,108
1913-14	19,035,512	20,023,932	39,059,444
1914-15	12,619,062	14,291,345	26,910,407
1915-16	12,498,004	24,637,178	37,134,182

Of the amount exported in 1915–16, it appears from a report by the United States Consul at

San José that the United Kingdom took 50·20 per cent., the United States 42·19 per cent., and the remainder was sent to France, Spain, Italy, Panama, and Chile. Almost half of the entire production is from the Province of San José.

man, woman, and child in continental United States.

The rate of growth as disclosed by the nine official censuses of manufactures taken between 1849 and 1914 (both inclusive), is shown in the following tabulation:—

Year.	Number of Establishments.	Wage-earners. (a)	Capital.	Wages.	Cost of Materials.	Value of Products.	Value added by Manufacture.
			Dollars.	Dollars.	Dollars.	Dollars.	Dollars.
1849	383	1,733	1,035,551	458,904	1,691,824	3,040,671	1,348,847
1859	541	2,340	1,568,478	688,423	2,990,186	5,361,100	2,370,914
1869	949	5,825	4,995,293	2,091,826	8,703,560	15,922,643	7,219,083
1879	1,450	9,801	8,486,874	3,242,852	17,125,775	25,637,033	8,511,258
1889	2,921	21,724	23,326,799	7,783,007	31,116,629	55,997,101	24,880,472
1899	962	26,866	26,319,000	8,020,453	35,354,208	60,643,946	25,289,738
1904	1,348	36,239	43,125,000	11,699,257	48,810,342	87,087,253	38,276,911
1909	1,944	44,638	68,326,000	15,615,388	81,150,773	134,795,913	53,645,140
1914	2,391	53,658	97,467,000	21,472,000	101,015,000	170,845,000	69,830,000

(a) Average number.

GROWTH OF AMERICAN CONFECTIONERY INDUSTRY.

To meet the American consumption of sweetmeats the year 1916 required between 175,000,000 and 200,000,000 dollars' worth of factory-made confectionery, and this in addition to the vast amounts of cocoa and chocolate other than confectionery that were consumed and to the home production of "taffy," "fudge," and other bonbons.

According to a statement recently published by the United States Department of Commerce, the confectionery industry of the United States has expanded with great rapidity. Sixty-five years ago less than 400 establishments were needed to supply the American demand for factory-made sweets. Their aggregate capital was little more than 1,000,000 dollars, and the value of their products not much over 3,000,000 dollars. On the basis of a population of 23,200,000, this meant an annual per caput expenditure of only 13 cents (there being practically no foreign trade in confectionery then). To-day, assuming that the industry has maintained during the last two years the same rate of growth as in the five-year period 1909–1914, the industry embraces over 2,500 establishments, represents the investment of 110,000,000 dollars capital, and turns out confections of various sorts having a total value of 185,000,000 dollars. On the basis of a population of 102,000,000, this means a net expenditure of 1·80 dollars a year for every

These figures reveal an increase of 524 per cent. in the number of establishments from 1849 to 1914; one of 2,996 per cent. in the average number of wage-earners; 9,312 per cent. in the capital invested; 4,579 per cent. in wages, 5,871 per cent. in the cost of materials; and one of 5,519 per cent. in the value of the products.

In the census returns the classification of "confectionery" covers the manufacture of all kinds of candy and confections, cake ornaments, popcorn balls or cake, chewing gum, salted nuts, stuffed dates, etc., but not the operations of establishments making primarily chocolate, cocoa and similar products, which are classified under the census designation of "chocolate and cocoa products." Prior to 1899 the statistics for the industry included the returns of the numerous small retail makers of confectionery, which accounts for the great decrease in the number of establishments between 1889 and 1899.

The American consumer much prefers his own American-made candy to the confections of other lands. Imports of foreign confectionery have never been large, and with few exceptions have been quite overshadowed by the exports; this the table below shows. Because of the diversity of sources from which the data were obtained, the "year" used in this tabulation is: For production, the calendar year; for imports and exports, the fiscal year ended June 30th; for population, the calendar year

following the one named, *i.e.* 1850, 1860, 1870, etc. :—

Year.	Production.	Imports.	Exports.	Population. (*a*)	Per capita Expenditure.
	Dollars.	Dollars.	Dollars.		Dollars.
1849	3,040,671	461	(*b*)	23,191,876	0·131
1859	5,361,100	1,243	(*b*)	31,443,321	0·171
1869	15,922,643	12,344	5,583	38,558,371	0·413
1879	25,637,033	6,537	32,274	50,155,783	0·511
1889	55,997,101	36,643	151,685	62,947,714	0·888
1899	60,643,946	31,797	603,170	75,994,575	0·790
1904	87,087,253	82,259	551,911	(*c*) 82,574,195	1·049
1909	134,705,913	80,953	716,727	91,972,266	1·459
1914	170,845,000	294,019	1,329,147	(*c*) 98,781,324	1·719

(*a*) Population of United States exclusive of outlying possessions.
(*b*) Not separately stated. (*c*) Estimated.

NEW PROCESS IN HAWAIIAN SUGAR INDUSTRY.

The invention of a new process for the recovery of sucrose from final molasses, which would mean a gain of at least 3½ per cent. in the commercial sugar crop of the Hawaiian Islands, is reported by the correspondent at Honolulu of the United States Department of Commerce. The inventor is Mr. J. N. S. Williams, who is field engineer to an American firm in the islands. The new process takes from the so-called "final molasses" approximately one-half of the 8 per cent. of sugar that heretofore has been considered an absolute loss. The additional cost for machinery will be slight, says Mr. Williams, but in the long run it will involve no additional cost to produce 3½ per cent. more sugar by the new process than is now taken from the juice in the production of second, third and fourth sugars. The process, he claims, will produce in one operation what now takes three operations, and at the same time will yield the additional sugar.

Mr. Williams's experiments with this process have extended over two years. The results, as summed up, are that final molasses boiled to 99 per cent. Brix will develop small grains representing practically the whole of the sucrose present in the molasses, that this grained sucrose can be recovered in large quantities with suitable equipment, and that this recovered sucrose may be converted into a marketable product.

The principle on which Mr. Williams has worked is that it is not the glucose gums or ash, but solely the water in molasses that has prevented the sucrose therein from crystallising. Removing the water, then, is the only method by which it can be made to give up its sucrose, he believes. This is the first step in the process—boiling the molasses to a practically complete absence of water.

The next important departure in the new process is the use of a high-speed centrifugal. On this point Mr. Williams explained that he had used a centrifugal built in 1905, which has been run to a speed almost twice as great as centrifugals ordinarily show. It is added that specially built centrifugals and apparatus for breaking the hard massecuite probably were the only machinery items on which there would be added cost.

THE DEVELOPMENT OF THE TEXTILE INDUSTRIES.

Dogs' Wool.—Industrial people have little time to spare over materials only available in very small quantities, and the discoverers of the utility of lap-dogs' "wool" will command more patience when they can offer it in parcels of some thousand pounds' weight. If the hair of dogs has not been used hitherto for making warm knitted comforts, the hair of rabbits certainly has. Hair plucked or combed from the Angora rabbit has been used, especially in France, for making light and costly wrappers for use in winter sports. Hair from most animals has been used in manufacture. The domestic ox in dying leaves a hair largely used in the pile of the cheapest plushes and sometimes in knitted underwear. The camel, the reindeer, the goat, and animals frankly unknown to those who use their produce, all furnish hair for one textile purpose or another. A distinction may be recognised between the pure purposes in which hair approximately all of the same kind is used to make relatively fine goods and the coarsest purposes known to commerce. Coming down to the dregs of manufacture, it can be said there are no questions asked. Given merchantable length and strength, the fibre goes to the blend that will make

the cheapest rugs or blankets. It is to be inferred that the British Dogs' Wool Association aims at producing from particular types of hair goods comparable with those made from wool of particular types of sheep, *e.g.* Iceland and Shetland.

Mixed Goods.—Perhaps the greatest technical advance made during the war has lain in the manipulation of mixed wool and cotton. Mixed yarns spun upon cotton machinery in imitation of French mule-spun worsted began to be produced in 1914, and their employment has spread because their character has been admired, and because of the need of economising wool to the utmost. The success attained in concealing the cotton must be as near perfection as it is likely to get, and is near enough in the best examples to deceive the senses of men who have been handling goods made from pure fine wool all their lives. The progress made in these delicate adjustments of old processes may well prove commercially more important than changes involving wider departures from established practice. The wool dress goods of the future will bear the marks of this experience for many years to come.

"Plains" and "Fancies."—It would have been acceptable to have the reports of the Committee on Textiles in considerably more detail, and it is to be supposed that before these can be published *in extenso* the situation confronting the industry may be materially different from that of 1916. The extracts published by the Board of Trade lose authority from a manner of publication which divorces them from the trains of thought in the evidence of witnesses. Regarding the general question of standardisation, we get the conclusion that the advantages of large-scale production are fully reaped in all staple branches of textile industry, but not in the minor branches of the large industries or in the silk, lace and cotton hosiery trades. The pronouncement covers a wide diversity of trade circumstances. The smaller trades commonly buy yarn which has been manufactured upon a thoroughly economical scale, and they are seen as a "host each making a small quantity of a multiplicity of articles, all making more or less the same articles each with separate buying, producing and selling organisations, all costing money and swelling overhead expenses." It is agreed that the difficulties are considerable, for fancy articles depend upon fashion for sale and lose their value when standardised or indefinitely multiplied. They are, indeed, fairly expensive articles to make, whether manufactured under one control or by numerous parties, and economy is best consulted in making only the right ones for the time. There is little doubt that the buyers of fancy goods value the freshness that comes of a multiplicity of origins, and they are accustomed to trace the inevitable family likeness in articles coming from one source. It is palpable, however, that the committee had in view the practice of making a little of everything—plain as well as fancy—and it is common experience that plains can most advantageously be made by standardised methods. Hitherto, however, plain textiles have not been as uniform as one might think. Some small and apparently immaterial feature is seized upon and demanded by customers here and there, so that even the maker of plain cloths works upon a surprising number of patterns and finds it profitable to do so.

Trade Combination.—Cartels are rather vaguely mentioned as affording a partial solution of the problems of standardisation in Germany, and cartels, or something like them, are held up as the hope of the silk, lace and hosiery trades. Makers of these goods are advised by the committee to try combination and co-operative selling in the foreign markets. It is advice to which manufacturers assent more readily in theory than practice, and it is to be observed that cartels are rarely found in any country except under stress of severe circumstances. Whether conditions after the war will favour independent action remains to be seen. There is an evident probability that collective action will be more imperative in some directions than in others; more, perhaps, in securing supplies and labour than in disposing of goods. At any rate for a period after the conclusion of peace, business can hardly need the stimulus of novelty of design.

Capital Outlays.—Shareholders in one of the woolcombing companies have been reminded that an immense sum will be required to put the plant and machinery into the same state of efficiency as in normal times. Depreciation has gone on fastest in the mills that have been most furiously worked, but it can be taken as a general rule that replacements or renewals of productive machinery are a good three years in arrears. When the work comes to be done the cost will inevitably be heavy, and the pressure upon machine-makers coming from foreign as well as home customers will exceed anything hitherto known. When it is understood that a spinner is asked 37*s.* 6*d.* for machinery that he last bought at 13*s.*, the influence upon capital outlay is manifest. Facts like this lend weight to the contentions advanced by manufacturers as to the need for special consideration at the hands of the tax-gatherers. Manufacturers wish to have left to them money to cover the expenses of replenishment, and exceedingly few of them will care to carry the cost of new plant at its full value in their books in the future. They will strive to write down the book values to some level approaching the normal, and the authorities will assuredly be pressed to countenance them in that prudent course. It has been the salutary ambition of most private textile enterprises to assume a low value for the mill and its contents, and it used to be true before the rise in values that cotton-mills which could not be built for five times the money stood in the books at 5*s.* per spindle. The utility of this drastic writing-down appears when the inevitable bad times are reached.

OBITUARY.

The Hon. Sir Sundar Lal, C.I.E.—Information has been received of the sudden death in India of Sir Sundar Lal in his sixty-first year.

Sir Sundar was leader of the Allahabad Bar, and he had also served the University there for many years, being at the time of his death its Vice-Chancellor. He had long represented the University on the Provincial Legislature, and was also a member of the Viceroy's Legislature. The successful organisation of the Benares Hindu University was due in no small measure to his energy, and he was its first Vice-Chancellor. He was also the first Indian to be appointed to the Bench of the Judicial Commissioner's Court of Oudh, and he was also for a time a Judge of the Allahabad High Court.

He was elected a Life Member of the Royal Society of Arts in 1901.

GENERAL NOTES.

M. Paul Lambotte's Lecture.—Fellows of the Society who were unable to be present at the meeting on March 13th will have another opportunity of seeing the remarkable series of lantern-slides shown in illustration of the appalling devastation wrought by the Germans in Ypres and its neighbourhood. M. Paul Lambotte, Directeur des Beaux-Arts au Ministère des Sciences et des Arts de Belgique, will repeat the lecture, which he delivered before the Society, at Kensington Town Hall on Tuesday, April 16th, at 5 p.m. The chair will be taken by the Mayor of Kensington, Alderman Sir William H. Davison, K.B.E., D.L. The proceeds of the lecture will be devoted to the Kensington Red Cross Hospital.

Formation of Diamonds.—For the past thirty years the Hon. Sir Charles Parsons has been conducting experiments on the formation of the diamond. The results of his work in this field of research—work which has a direct bearing on many branches of pure and applied science—are to be made known for the first time at the eighth annual May Lecture, which he is to give before the Institute of Metals on May 2nd. In view of the special character of the occasion, the Council of the Institute of Metals have decided to make this an open meeting. Those desiring to be present should apply, enclosing a stamped and addressed envelope, for cards of invitation to Mr. G. Shaw Scott, M.Sc., 36, Victoria Street, S.W. (1)

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m. :—

April 17. — Frank Stuart Courtney, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England, "Agricultural Machinery." Dr. J. A. Voelcker will preside.

April 24.—Sir Major Robert Armstrong Jones, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons in Social and Medical Reconstruction." The Right Hon. Lord Sydenham, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

May 1.—George Martineau, C.B., "Sugar from several Points of View." The Right Hon. Lord Balfour of Burleigh, K.T., G.C.M.G., G.C.V.O., will preside.

May 8.—John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

May 15.—Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

May 29.—Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." Sir William A. Tilden, D.Sc., LL.D., F.R.S., will preside.

Indian Section.

Thursday afternoons, at 4.30 p.m. :—

April 18.—Alfred Dickinson, M.Inst.C.E., "Water Power in India." The Right Hon. Lord Lamington, G.C.M.G., G.C.I.E., will preside.

May 30.—Hon. Sir Dinshaw E. Wacha Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

Colonial Section.

Tuesday afternoon, at 4.30 p.m. :—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana." Sir Everard im Thurn, K.C.M.G., C.B., will preside.

Cantor Lectures.

Monday afternoons, at 4.30 p.m. :—

J. Young, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day."

Syllabus.

Lecture II.—April 15.—Other high-explosive mixtures and their uses — Chlorate mixtures — Nitro-cellulose and nitro-glycerine, and mixtures containing them—Military smokeless powders.

Lecture III.—April 22.—High explosives used for shell filling—Methods of detonation—Initiators of detonation — Tests applied to explosives — Miscellaneous.

Special Lectures.

A special course of three lectures on "The Freedom of the Sea" will be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m

LECTURE I.—By GERARD FIENNES. Chairman, J. L. GARVIN.

Syllabus.

THE FREEDOM OF THE SEAS.

Freedom without Law. — The first maritime peoples—The Viking Age—Edward III. and the sovereignty of the seas—The Hansa—The Italian Republics in the Mediterranean.

Law without Freedom.—The discovery of the passage round the Cape of Good Hope and of America—The Bull of Alexander VI.—Henry VII.'s licence to the Cabots—Elizabeth's views—The English and Dutch—The war of Jenkins's Ear—The mercantile system—Berlin decrees—Orders in Council.

Law and Freedom.—Britain's work—Freedom "made in Germany."

LECTURE II. — By SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905-12. Chairman, LORD SANDERSON, G.C.B., K.C.M.G.

Syllabus.

THE FREEDOM OF THE SEA IN WAR.

The breakdown of International Law due to unpractical theories—Effect of war on the Freedom of the Seas—Limitations of neutral commerce with the enemy—Rule of 1756—All interference with neutrals based on prevention of assistance to the enemy—"Free ships, free goods": the neutral doctrine essential to maintain the enemy's fleet—Foundation of a spurious Freedom of the Sea claimed by enemies and neutrals: consistent opposition to the doctrine by England—The armed neutralities—American War of Independence—Bonaparte's theories—Immunity of private property at sea—Declaration of Paris—Maintenance of English principles of belligerency essential to an effective League of Nations.

LECTURE III.—By JOHN LEYLAND. Chairman, The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S.

Syllabus.

THE GERMAN "FREEDOM OF THE SEAS."

Britain the great upholder of the Freedom of the Seas—The meaning of the term—How it was regarded by Grotius—How we came to be denounced as the "tyrants of the sea"—The attitude and policy of Napoleon—His claim to be the liberator from tyranny—The modern German claim a protest against British sea-power—An analysis of the claim—Its real meaning—The view held and expressed in the United States—The agreements and understandings with Prussia—President Wilson's declaration—How it is in conflict with the German claim—The need of a right understanding of the subject.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 15 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. J. Young, "Military Explosives of To-day." (Lecture II.)

Victoria Institute, Central Buildings, Westminster, S.W., 4.30 p.m. Rev. Canon J. A. MacCulloch, "The Gnostic Conception of the Cross."

Engineers, Cleveland Institution of, at the Literary and Philosophical Society, Middlesbrough, 7.30 p.m.

Geographical Society, Kensington-gore, W., 5 p.m. Mr. G. T. McCaw, "Resection in Survey—the First Problem."

TUESDAY, APRIL 16...Illuminating Engineering Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m. Professor W. M. Bayliss, "Light and Vision: the Physiology of the Retina."

Petroleum Technologists, Institution of, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m. Drs. A. E. Dunstan and F. B. Thole, "Relation between Viscosity and Chemical Constitution of Lubricating Oils."

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m.

Japan Society, 20, Hanover-square, W., 3.30 p.m., Mrs. W. Weston, "Fuji San Old and New."

WEDNESDAY, APRIL 17... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. F. S. Courtney, "Agricultural Machinery."

Meteorological Society, at the Institution of Civil Engineers, Great George-street, S.W., 5 p.m. 1. Mr. E. G. Bilham, "The Variations of Underground Water-level near a Tidal River." 2. Mr. J. Fairgrieve, "Suggestions as to the conditions precedent to the occurrence of Summer Thunderstorms with special reference to that of June 14th, 1914."

Geological Society, Burlington House, W., 5.30 p.m. Mr. A. E. Trueman, "The Evolution of the Lifaroceratidæ."

Literature, Royal Society of, 2, Bloomsbury-square W.C., 5.15 p.m. Lecture by Professor W. de la Mare.

Electrical Engineers, Institution of (Local Section), University, Birmingham, 7 p.m. Mr. E. C. McKinnon, "Large Batteries for Power Purposes."

THURSDAY, APRIL 18...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Indian Section.) Mr. A. Dickinson, "Water Power in India."

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. Professor J. P. Hill, "Narrative of the Percy Sladen Expedition to Brazil in 1913."

Chemical Society, Burlington House, W., 8 p.m. Lecture by Sir Henry Miers.

Royal Institution, Albemarle-street, W., 3 p.m. Lieut.-Colonel C. S. Myers, "Present-day Applications of Experimental Psychology." (Lecture II.)

Electrical Engineers, Institution of, at the Institution of Civil Engineers, Great George-street, S.W., 6 p.m. Mr. L. Andrews, "Overseas Distribution of Engineering Appliances."

Mechanical Engineers, Institution of, Storey's-gate, Westminster, S.W., 8 p.m.

FRIDAY, APRIL 19...Royal Institution, Albemarle-street, W., 5.30 p.m. Major G. I. Taylor, "The Use of Soap Films in Engineering."

SATURDAY, APRIL 20...Royal Institution, Albemarle-street, W., 3 p.m. Professor E. H. Barton, "Musical Instruments Scientifically Considered." (Lecture II.)

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—April 12, 1918.

No. 3413. APRIL 19, 1918. Vol. LXVI.

JOURNAL

OF THE

ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

MEETINGS FOR THE ENSUING WEEK.

Monday, April 22 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Cantor Lecture.) Mr. J. Young, "Military Explosives of To-day." (Lecture III.)

Geographical Society, Burlington - gardens, W., 8.30 p.m. Miss M. H. Mason, "The Transkei."

Tuesday, April 23...London Society, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m. Rev. Canon Carnegie, "St. Margaret's Church, Westminster."

Royal Institution, Albemarle-street, W., 3 p.m. Professor A. Keith, "Barrow Explorers." (Lecture I.)

Civil Engineers, Institution of, Great George-street, S.W., 5.30 p.m. Annual General Meeting.

Zoological Society, Regent's-park, N.W., 5.30 p.m. 1. Dr. J. A. Murray, Report on the Deaths in the Gardens during the Year 1917. 2. Professor Wood-Jones, Exhibition of specimens illustrating the effects of Rickets.

Statistical Society, 9, Adelphi-terrace, W.C., 5.15 p.m. Professor Commendatore Attolico and Captain F. Giannini, "The Industrial Position of Italy."

Wednesday, April 24 ... ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Major Sir Robert Armstrong-Jones, "Mental Effects of the War and their Lessons in Social and Medical Reconstruction."

Sanitary Institute, 90, Buckingham Palace-road, S.W., 5 p.m. 1. Mr. F. Baines, "Housing: Planning and Materials, Permanent and Semi-Permanent." 2. Mrs. Sanderson Furness, "Housing: Fitments and Conveniences."

Colonial Institute, Caxton Hall, Westminster, S.W., 4 p.m. Lieut. C. H. S. Reis, "The Remarkable Development of Argentine Agriculture."

Thursday, April 25...Royal Society, Burlington House, W., 4.30 p.m.

Cold Storage and Ice Association, at the Royal Society of Arts, John-street, Adelphi, W.C., 5 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Isambard Owen, "Rheims Cathedral." (Lecture I.)

Electrical Engineers, Institution of, Victoria Embankment, W.C., 6 p.m. Mr. E. C. McKinnon, "Large Batteries for Power Purposes."

Concrete Institute, 296, Vauxhall Bridge-road, S.W., 5.30 p.m. Mr. J. H. Deane, "The Charterhouse Street Cold Stores of the Port of London Authority."

Friday, April 26...Royal Institution, Albemarle-street, W., 5.30 p.m. Sir A. Daniel Hall, "Food Production and English Land."

Physical Society, Imperial College of Science, South Kensington, S.W., 5 p.m.

Saturday, April 27...Royal Institution, Albemarle-street, W., 3 p.m. Professor H. F. Newall, "Modern Investigations of the Sun's Surface." (Lecture I.)

Journal of the Royal Society of Arts.

No. 3,413. VOL. LXVI.

FRIDAY, APRIL 19, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

MONDAY, APRIL 22nd, at 4.30 p.m. (Cantor Lecture.) J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day." (Lecture III.)

WEDNESDAY, APRIL 24th, at 4.30 p.m. (Ordinary Meeting.) SIR MAJOR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons in Social and Medical Reconstruction." The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

Monday afternoon, April 15th; MAJOR-GENERAL SIR DESMOND D. T. O'CALLAGHAN, R.A., K.C.V.O., in the chair. Mr. J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, delivered the second lecture of his course on "Military Explosives of To-day."

The lectures will be published in the *Journal* during the summer recess.

SEVENTEENTH ORDINARY MEETING.

Wednesday afternoon, April 17th; DR. J. A. VOELCKER in the chair. A paper on "Agricultural Machinery" was read by Mr. FRANK STUART COURTNEY, M.Inst.C.E., Consulting Engineer to the Royal Agricultural Society of England.

The paper and discussion will be published in the *Journal* of May 10th.

INDIAN SECTION.

Thursday afternoon, April 18th: The RIGHT HON. LORD LAMINGTON, G.C.M.G., G.C.I.E., in the chair. A paper by Mr. ALFRED DICKINSON, M.Inst.C.E., on "Water Power in India" was read by Mr. E. S. WOOLLARD MOORE Assoc.M. Inst.C.E.

The paper and discussion will be published in the *Journal* of May 17th.

PROCEEDINGS OF THE SOCIETY.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, March 14th, 1918; The RIGHT HON. J. AUSTEN CHAMBERLAIN, M.P., in the chair.

The paper read was—

ENGLISH COMMERCE WITH INDIA, 1608–1658.

By WILLIAM FOSTER, C.I.E.,
Registrar and Superintendent of Records, India Office.

The calendaring of the India Office records has now reached a point from which it is possible to look back upon fifty years of British trade in the East. It was a period of many experiments and many failures; but by its close, so far as India itself was concerned, the trade had settled down upon the main lines on which it was conducted, with striking success, during the remainder of the seventeenth century. The subject is a complicated one, for the operations of the East India Company's servants extended from Arabia and Persia on the west to China, Japan, the Philippines, and the Moluccas on the east, while many of the lines of traffic were interwoven in a somewhat confusing manner with the direct trade between India and England; and since the time at my disposal will not permit me to survey the whole field, I have thought it best to confine myself to the consideration of the actual exchange of commodities between our own country and its future dependency. This is the aspect of most interest to a British audience, and it is one

concerning which little is to be found in the ordinary text-books.

It is a matter of common knowledge that a direct commerce with the Indian peninsula was not the main object of the East India Company at the time of its establishment in the year 1600. The immediate aim of its promoters was to compete with the Dutch in fetching from the Malayan Archipelago the pepper and spices which were so much in demand in the Europe of that day. Consequently the goal of the Company's fleets was for long the port of Bantam, in Java, which was at once a good centre for pepper and a convenient starting-point for the further voyage to the Spice Islands. It was, however, quickly discovered that English commodities were in small demand in those parts, while, on the other hand, the products of India, especially calicoes, found eager purchasers; and thereupon it was arranged that the outgoing fleets should call at Indian ports, in order to dispose of their European goods and to procure in return some more suitable for the Far Eastern markets. From this resulted the foundation of factories—as the Company's commercial establishments were termed—in the dominions of the Mogul Emperor of Northern India, particularly at Surat, the chief port of Gujarat. This was in 1608, and a few years later trade was opened up for a like purpose on the other side of India, where a factory was settled at Masulipatam, the chief port of the independent kingdom of Golconda. The latter commerce was for long entirely subservient to the needs of the Bantam market; it was not until 1629 that a vessel was sent direct from England to the Coromandel Coast, and none went home from thence until twenty years later. As regards the trade with Western India, the next stage was for one or two of the outward-bound fleet to turn back at Surat, carrying home Indian and Persian products, while the remaining vessels went on to Bantam. This development took place in 1615, nearly seven years after the first arrival of an English ship at an Indian port; and that date may be taken as the real commencement of the direct trade between the two countries, though already many English commodities had been sent out for sale in the Mogul's dominions, while a certain amount of Indian products had reached the home markets by way of Bantam.

When the Company's servants at Surat had to decide what goods to send for England, their choice naturally fell in the first place upon indigo, which was already in some demand in Europe for dyeing purposes. By far the most important English export was woollen goods (chiefly broadcloth), and the making, dressing, and dyeing of these formed the chief industry of the nation. Blue was a favourite colour; yet a suitable dye was not easily obtainable. For a long time the principal agent employed was woad, of which considerable quantities were imported from the Continent for that purpose. As an alternative, logwood for a while came into favour, but although this afforded a wide range of tints, its colours could not be fixed, and on this ground its use was forbidden by Act of Parliament in 1581 and again in 1597.* In the meantime a more satisfactory substitute had been found in indigo, which was brought from India to Lisbon by the Portuguese and from Turkey to London by the ships employed in the rising trade with the Levant, and was in some demand, not only in England, but also in France and other Continental countries. So promising did this new commodity appear to be that in 1582 we read of instructions being given to an English traveller to endeavour to procure in Egypt some indigo plants or seeds, with a view to their being acclimatised in England. Hence it is not surprising to find that in 1615 the "Hope" took home from Surat over 1,400 bales of indigo, procured chiefly at Ahmadabad. The rest of her lading consisted of calicoes, cotton yarn, carpets, ginger, aloes, etc.

Thenceforward indigo became the principal constituent of the cargoes sent home from Surat. The chief centres of supply were Sarkhej, near Ahmadabad, and Biana, near Agra. The methods of manufacture in these districts were different, the result being in the case of the former a coarse kind of indigo, often much adulterated, while the Biana variety was hard and of a superior quality. The distinction was known in London some years before the arrival of the "Hope," for in April, 1609, we find the East India Company writing that Sarkhej indigo was

* Acts 23 Eliz. c. 9, and 39 Eliz. c. 11. The prohibition was not formally removed until 1662 (13 & 14 Chas. II. c. 11). It seems, however, to have been disregarded, for in July, 1615, a certain Richard Giles obtained a patent authorising him to enforce it by seizing and destroying logwood wherever found. The East India Company naturally approved of his activities, as tending to encourage the use of indigo; and in October, 1617, they gave him £20 towards his expenses, while in the following July they agreed to pay him a regular tariff on all his seizures. They also induced the King to issue a proclamation threatening punishment to all concerned in the use of logwood; and a further proclamation to the same effect appeared in 1636. The statement made by some writers that the use of indigo was prohibited by Act of Parliament appears to have been due to a confusion with the ban placed upon logwood.

then worth 5*s.* a pound, while the Lahore kind (by which they meant the Biana indigo, which then came mostly overland from Lahore) was fetching 8*s.* When once the importation by the Company had become established, these prices dropped to about 5*s.* 6*d.* or 6*s.* for the Biana variety, and 4*s.* or 4*s.* 6*d.* for that from Sarkhej. In March, 1646, when the dyeing industry was doubtless disorganised by the Civil War, the Company wrote that these rates had gone down to 4*s.* in the one case and 3*s.* 4*d.* in the other, and that, unless an improvement took place, the indigo would have to be of specially good quality to be worth importing. Some nine years later the price had improved to about 4*s.* for Sarkhej and nearly 6*s.* for Biana indigo. Besides these two kinds, we hear of a medium quality obtained from Sind from about 1638 onwards; in 1646 this was fetching 3*s.* 4*d.* a pound, and two years later 2*s.* 8*d.* Some indigo received from the Coromandel Coast sold in 1644 and 1645 for a little over 1*s.* 3*d.*, and in 1657 for 1*s.* 5½*d.* It was evidently of a very inferior quality.

The comparatively high price fetched by this article led to an attempt in England to utilise indigo dust (bought at a cheap rate from the Company) by working it up into an imitation of the ordinary balls or cakes. In July, 1634, William Bolton obtained a patent for this process, much to the indignation of the Company, whose remonstrances were so vigorous that in the following December the patent was cancelled. It is worth noting that Bolton alleged that the Biana indigo, as sold by the Company, was too hard for general use, and that his patent covered a process by which this was soaked and ground down, being afterwards made up, with the addition of indigo dust, into a substance more nearly resembling Sarkhej indigo. The latter kind, by the way, was the one most favoured by English dyers, though they admitted that one pound of the Biana variety went as far as a pound and a half of the Sarkhej indigo.

The prices at which the indigo was purchased in India varied according to the abundance or deficiency of the crops, and the amount of competition on the part of buyers. To avoid the enhancement due to the latter cause, the Dutch and English merchants on several occasions combined to buy in common, though at other times the competition between them was severe. On an average the cost appears to have been about 1*s.* a pound. Gerard Malynes in 1623 put it at 1*s.* 2*d.*, and the average proceeds in England at 5*s.* At either rate, allowing 2*s.* or 2*s.* 6*d.* for shipping and other charges, there was still a fair margin of profit. In 1652 we find the Surat factors writing to the Company that indigo "hath heretofore bin your most gainefull comodity."

The adulteration to which indigo was subjected by the makers, particularly by the admixture of sand and earth, led to many complaints from the Company. The Surat factors in 1644 explained that this was a long-standing practice, the object being to give greater consistency to the indigo. As their employers were still unsatisfied, the factors in 1646 bought a quantity of indigo leaf themselves, and had it manufactured under their own superintendence; but though the quality was improved, the cost was, if anything, higher than if the indigo had been purchased in the usual way, and after a second attempt, two years later, the experiment was abandoned.

A large proportion of the indigo imported by the Company was sent to the Continent, much of it going to the Mediterranean for sale in Southern France and Italy, while a certain quantity found a market at Hamburg, Danzig, and even in Holland, though the Dutch were, of course, bringing their own supplies from India. In 1625 it was stated that the merchants of the Turkey Company, who at one time had regularly imported raw silk, indigo and spices into England from the Levant, were now actually buying those goods in London, and carrying them to the Mediterranean. This re-exportation of indigo continued down to the end of the period with which we are dealing, in spite of the wars that were waged with various Continental powers in the time of Charles I. and the Commonwealth.

Meanwhile the Company's trade in this article was already being threatened with competition from the West Indies. As early as January, 1633, mention is made in the Court Minutes of some indigo from Guatemala having been brought into England from Spain; and later on the English planters in the West India Islands, as well as in Carolina and Georgia on the mainland, cultivated the plant with some success, though, according to Macpherson ("European Commerce with India," p. 201), they were never able to produce indigo equal to that of Guatemala or of San Domingo. All these competitors had a great advantage over the East India Company in the cost of transporting their produce to the European markets, and during the latter part of the seventeenth and the early part of the eighteenth centuries the importation from India was limited to the

better qualities, grown in the Agra neighbourhood and purchased at Surat. The anarchy that set in after the death of Aurangzeb doubtless restricted the supply and enhanced the cost; and after the year 1724 the Company omitted indigo from the annual list of commodities to be purchased. In 1729 the Bombay Council sent home (unasked) a large quantity, which could only be sold at a very heavy loss; and thereupon the directors peremptorily forbad any further dealing in the article. For half a century indigo ceased to figure among the Company's imports; and then a change in the situation made it once more an object of interest. About the middle of the eighteenth century its cultivation in the West India Islands was abandoned—according to Macpherson, because of a high duty imposed upon it, but Sir George Watt suggests that the real reason was the higher profits yielded by sugar and coffee. This left the markets to the Americans and the Spaniards, and both sources of supply were stopped in 1775 by the War of Independence, in which Spain took sides against Great Britain. The consequence was a revival of the demand for the Indian commodity, and the establishment, about 1779, under the Company's auspices, of a flourishing indigo industry in Bengal. The subsequent history of this is well known.

Returning from this digression, we have now to examine the second branch of the Company's importations from India in the early days, viz., the cotton goods generically termed at home calicoes. In this case there was little or no existing demand for the commodity. The ground was occupied by the linens imported from France, the Netherlands, and Germany—as still evidenced by the names of hollands, silesias, lawns (from Laon), and cambrics (from Cambrai). The British and Irish linen industries were as yet non-existent, and so the gradual displacement of the foreign linens by Indian calicoes was viewed with complacency, particularly as a large proportion of the latter were re-exported—a traffic which, beginning with Turkey (where cotton goods were, of course, well known), spread gradually into other countries which had hitherto used linens. In August, 1623, the Deputy-Governor of the Company (Morris Abbot) reported a conversation which he and Mr. Thomas Mun had had with King James, who asked "what vent they had for the greate masse of callicoes [that] came yerelye. They answered that much of it is very usefull and vendes in England, whereby the prizes of lawnes, cambrickes, and other linnen cloth are brought downe; for the rest, England is now made the staple for that comoditie, which having first served His Majesties dominions, the overplus is transported into forrayne partes in the nature of a home bredd commoditie. The King approoved exceedingly thereof, and said that this was the ready way to bring treasure into his kingdome." In the following April Abbot (now Governor) declared that, whereas formerly England paid to the foreigner for hollands, lawns, and cambrics £500,000 per annum, now half of this outlay was saved by the importation of calicoes; and about a year later he told the Company that "the commodities of Zuratt doe vend heer much better then in former tymes; for example . . . callicoes . . . hath found such vent in forreyne parts as, if the Company had 100,000 or 200,000 peeces, they wold bee uttered in short time."

By 1630 the Company were ordering from Surat 100,000 to 120,000 pieces of white calico alone. Then came the depopulation of Gujarat by the terrible famine of 1630–32, which ruined the trade for a time, as calicoes became too dear for the London market.* In October, 1636, the Company wrote that the absence of supplies had "caused our linnen drapers here to find out other sorts of cloath to supplie the wants of their accustomed sorts of callicoes," and consequently "our callico trade hath suffered much in its wonted use and expence, and will require some tyme to bring that commodity into worth and reputacion againe." Eighteen months later they declared that all sorts of calico were out of favour in England, and that those bought were chiefly used for "dyeing into colloures." However, as time went on the industry gradually revived in Gujarat; while the opening up of English trade in Sind (1635) provided a fresh source of supply of good and cheap calicoes, and there was also a steady importation into England of piece-goods from the Coromandel Coast, which found favour in France and other Continental countries.

One effect of the famine of 1630–32, in which so many skilled weavers perished, was a great deterioration in the quality of the cloth produced; and this again operated unfavourably upon the demand in Europe. Writing in November, 1641, the Company declared that calicoes had hardly yet recovered their former

* Owing to the heavy charges incurred for shipping and factors, besides expenses at home, the Company held it necessary to realise three times the prime cost of their calicoes, if they were to be considered profitable.

reputation, lost by the poor making and bleaching of previous consignments, while the enhanced price made it difficult to compete in the London market against "the Germanie, Scotch, and French lynnens." The difficulty was aggravated by the general depression of trade which set in about 1640, and was intensified by the Civil War that followed; and the Company, finding no demand for the calicoes sent home, repeatedly distributed them to its members by way of dividend, leaving the recipients to get rid of them as best they could. By 1653 the demand had revived, possibly owing to the stoppage of linen imports as the result of the war with Holland; and in September of that year the Company wrote to the Surat factors to send as many calicoes as they could procure. Then came the period of open trade, when private English ships resorted freely to Indian ports in defiance of the Company's privileges. The resulting competition forced prices up in the East and down in Europe. However, the grant of a fresh charter by Oliver Cromwell in 1657 improved the Company's prospects, and we leave them confident of a great future for the trade in calicoes—a confidence which was soon justified.

It is interesting to note how the endeavours of the Company and its servants to procure calicoes of suitable dimensions and quality broke against the conservatism of the Indian weaver. At the beginning of 1628 the Surat factors wrote that they had tried in vain to secure the more substantial making of the cloth. The weavers objected, on the score that more yarn would be used, while the price of the finished article would not increase in proportion, adding that they could sell all they made in their usual fashion to other buyers, if the English did not want them. Some twenty years later the Company demanded cloths of special lengths and breadths; but again the makers demurred, pointing out that such goods would not easily find a market elsewhere, if rejected for any defect. Numerous complaints from London show that the calicoes provided varied considerably in size and in quality, while no improvement could be secured, because the demand in India from other and less fastidious quarters was sufficiently great to warrant the producers in refusing to alter their traditional methods.

Before passing from the subject of cotton, something may be said regarding the references to cotton yarn and raw cotton that occur in the Company's records at this time. Yarn was a fairly constant article of import from 1615 onwards, partly for export to France and Holland, and partly to meet the home demand. From 1616 to 1628 the price obtained by the Company was about 2*s.* 6*d.* a pound. In the latter year no less than 525 bales came home from Surat; and in March, 1630, the Company wrote that they could sell from 600 to 700 bales yearly. Then came a check. The Gujarat weavers objected to the English merchants competing with them for yarn, and combined to withhold their cotton cloth until the factors agreed to stop their buying; while on top of this trouble came the great famine. In spite of this the supply was kept up and good prices were realised in England. The Company wrote in November, 1641, that "of late workemen here have found many uses" for the yarn, and that the finer qualities were much in demand. In 1650 orders were sent out to reduce the supply, with the result that in 1652–55 we find prices at home ranging from 4*s.* to 4*s.* 4*d.* the pound. Then came a drop to the old level of little more than half-a-crown, probably because of heavy importations by private traders.

Raw cotton, or cotton-wool, figures at the Company's sales as early as November, 1621, but it was merely "packing wooll," which had apparently been brought home wrapped round the bales of piece-goods for their better protection, and it fetched only 6*d.* a pound. In 1622 an order was sent to Surat for a special supply, with the result that we find sales effected in 1624 at 14¼*d.* and in the following year at 13*d.* per pound. Some difficulty was experienced as regards stowage aboard the ships, since the commodity was too bulky to waste space upon it, if more profitable goods were available. In 1628, and again in 1636, the Surat factors urged that implements should be sent out for compressing the bales (as was done, they said, in Turkey); but no notice was taken of these suggestions, and the cotton continued to be sent home, if at all, loose in the hold, much to the detriment of its condition when received. By this time the manufacture at Manchester of goods, such as fustians, in which cotton was mingled with other materials, had become well established. The cotton used for this purpose came, however, from Cyprus and Smyrna. With a commodity at once so cheap and so bulky, the cost of freight was the most important factor in the sale price; and it was probably for this reason that the Company made no attempt to compete with the Levant traders. For the remainder of the period with which we are dealing, the sales at the East India House of raw

cotton were only of small quantities originally used in packing, which fetched from about 4*d.* to 15*d.* per pound, according to its condition and the momentary demand for it. The omission in 1650 of cotton-wool from the list of goods in which private trade was prohibited is a further proof of the small importance attached by the Company to this article of commerce.

Raw silk is the next item on our list of the Company's imports. The efforts made by James I. to encourage the manufacture of silk in England are well known, and to the demand for the raw material the East India merchants responded at first by importing Chinese silk from Bantam. In 1616, however, their servants succeeded in establishing trading relations with Persia, where large quantities of silk were produced in the provinces bordering upon the Caspian Sea. The sale was a royal monopoly; but the Shah was eager to prevent the traffic from passing through the dominions of his enemy, the Turkish monarch, and he welcomed with effusion the overtures made by the English, and later by the Dutch, for its diversion to an all-sea route. The first consignment went home from Surat in 1619, and sold for 26*s.* 10*d.* the great pound of 24 oz. As the cost in Persia was only from 8*s.* to 9*s.* a pound, this yielded a handsome profit, and the Company showed some eagerness to develop the trade. In 1622 Persian silk to the value of £93,000 was received from Surat, and in the following year this figure rose to £97,000. Much of the silk seems to have been exported to France, Italy, and the Low Countries, in spite of competition from that brought overland from Persia to Aleppo, as well as from that imported direct into Holland. However, the Persian officials made the most of their opportunities by debasing the quality and raising the price; and in January, 1625, it was noted that the cost in Persia was now 12*s.* 6*d.* per pound, while the proceeds in England were not more than double that figure. The Dutch, moreover, were competing vigorously in its purchase, and probably their imports were lessening the demand in England for export to the Continent. In November, 1626, the Surat factors pointed out that their other goods yielded more profit than silk, and advised that their colleagues in Persia should abstain from further purchases, remitting instead to Surat, for investment there, any money realised by the sale of English goods. Evidently, however, a certain quantity of silk still went home, but the price dropped gradually to 15*s.* a pound, on a prime cost of 10*s.* 6*d.*, and the Company in 1641 forbad any further investment. As already noted, this was a period of general depression of trade in England, and such an article of luxury as silk was bound to feel its effects. By 1648, however, prices had risen again, and orders were sent out for a fresh supply; while, during the war with Holland in 1652–54, as much as 27*s.* 6*d.* and 28*s.* per pound was obtained in London for the small quantity of Persian silk brought home. By July, 1656, the price was down again to 18*s.* 8*d.*; and, writing to Surat in March, 1657, the Company said that raw silk was in small demand.

In addition to Chinese and Persian silk, the Company during this period imported a certain quantity from Bengal. As early as 1619 some samples, procured at Agra, were sent home from Surat; and these crossed a letter from the Company, in which the factors were encouraged to furnish a good supply, provided that the silk was obtainable in long skeins and at a cost of not more than 7*s.* a pound. In reply it was stated that supplies were not regularly available at Agra, and that the silk was mostly in small and short skeins which it would be unprofitable to rewind. The despatch of a couple of merchants from Agra to Patna in 1620 gave an opportunity for fresh investigations. They reported that silk could be provided at a cost of about 6*s.* 6*d.* a pound, but that none could be procured that came up to the Company's requirements in other respects. With commendable enterprise they started a workshop in which an attempt was made to wind the silk from the cocoon in the manner desired; but no success attended their efforts, and the recall of the factors in 1621 put an end to the experiment. The Company had already made inquiries from the Masulipatam factors whether Bengal silk could be obtained by that route; the reply was, however, unfavourable, and so for a time all thought of that commodity was abandoned. Peter Mundy, who was sent from Agra to Patna in 1632, expressed the opinion that raw silk could be purchased elsewhere of better quality and at lower rates.

The establishment in the following year of English factories in Orissa seemed to open up a prospect of procuring Bengal silk by a new route. In 1634 we hear of trials being ordered at home of two bales of that commodity; but as nothing more is said upon the subject, we may conclude that the results were unfavourable. Eleven years later some Bengal silk (probably in poor condition) was sold by the Company at the low price of 9*s.* 1*d.* per pound.

About this time the cessation of supplies from Persia seems to have revived interest at home in the silk of Bengal, for in 1647 a letter was addressed to Surat making fresh inquiries on the subject. Some samples, procured at Agra, were accordingly sent home, and fetched 18*s.* per pound of 24 oz.; but, writing early in 1650, the Surat factors said that they would refrain from further purchases, as they considered the Persian silk, the trade in which had now been resumed, to be equally profitable. The establishment of a factory at Hugli in 1651 enabled the merchants there to provide Bengal silk at cheap rates and to pick out the better qualities, with the result that in 1653 the Company were getting from 25*s.* 3*d.* to 32*s.* 3*d.* a pound. This appreciation, however, was probably due in part to the war with Holland, for by 1657 the price had fallen to 16*s.* To follow the subsequent development of this traffic, as factories were established at Patna and other places in Bengal, would carry us beyond our present limit; but it may be noted that, until improved methods of winding were introduced under the Company's direction, about the middle of the eighteenth century, Bengal silk found little favour in England, and its use was chiefly restricted to the manufacture of sewing silks and other items of haberdashery.

In manufactured silks the Company appear to have taken little interest, though some of the piece-goods imported consisted of mingled cotton and silk; while quilts, made often of both materials, figure in the early cargo lists. As regards other textiles, there was at first a considerable importation of carpets, either bought ready-made or else manufactured to order at Agra. In 1619, however, the factors at that place wrote: "We perceave, by experience of a few bespoken here, that the tardines, slownes, and poverty of the workemen to be such that it is endles labour to bespeake them, and those bespoken to cost dearer then others ready made," adding that, when finished, the carpets specially manufactured were neither so well made nor so good in colour as those imported from Persia. In subsequent years purchases were made by the factors in the latter country; but by 1628 the Company had forbidden further investments in this article, and from 1632 carpets were allowed to be brought home as private goods. It is perhaps unnecessary to mention that at this period Oriental carpets were chiefly used as tablecovers, not trodden under foot.

As regards pepper, for a long time the favourite sources of supply for England were Java and Sumatra, both because the cost was lower and because access to the pepper ports on the western side of India was rendered difficult by the hostility of the Portuguese. As, however, the Dutch hold on the Malay Archipelago tightened, the English East India Company became more and more desirous of obtaining Indian pepper, especially as its superior quality enabled a slightly higher price to be demanded at home. In 1622 and 1630 Malabar pepper was costing in India about 6*d.* a pound, which was more than double the price at Bantam; but it was shot loose into the ships' holds and the expense of freight was therefore small; while at home it realised from 1*s.* 7*d.* to 1*s.* 9*d.* per pound. The bulk of that brought to London was evidently re-exported. In 1631 one merchant purchased the whole quantity received, to the value of from £30,000 to £35,000, and two years later the bargain was repeated with another merchant, for the express purpose of sending the pepper abroad. The conclusion in 1635, at Goa, of a convention between the Viceroy and the English President of Surat, opened the Portuguese harbours to English ships, and facilitated access to the Malabar pepper ports. Courteen's Association, which was largely founded to take advantage of this agreement, at once started factories at Bhatkal and Rajapur, whence large quantities of pepper were sent to England. Not to be outdone, the Company ordered their servants at Surat to provide a good supply; but most of the pepper procurable there came overland from the Balaghat and was consequently dear; while, as prices at home steadily declined, the trade was soon deemed scarcely worth following. Between 1644 and 1650 the Company found it expedient to ship pepper to Italy, owing to the small demand in England itself. The competition of private traders lowered prices still further, and in August, 1657, the Company were getting only 7*d.* per pound. In the previous November it was stated that the consumption of pepper in England was less than one-fifth of the 7,000 bags imported annually; that its average cost in the Indies was 3*d.* a pound, which was raised to 10*d.* by shipping and other charges; and that the remaining 5,600 bags, if sold on the Continent, would realise £70,000 at 1*s.* 8*d.* per pound. Evidently in this, as in many other branches of the Company's trade, reliance was placed rather on the export market than on the actual home demand.

Of spices in general, India was rather a

consumer than a producer. Cinnamon was occasionally obtained by English merchants at some of the Malabar ports or bought surreptitiously from the Portuguese, especially when the frequent blockades of Goa by Dutch fleets prevented its transmission to Lisbon; but the conclusion of a truce between Holland and Portugal in 1641 put an end to this traffic. The renewal of the war in 1652 was followed by a sustained attack by the Dutch upon Ceylon. Colombo was captured in 1656, and the other Portuguese settlements in the island were quickly mastered, with the result that the cinnamon trade, like that in other spices, became virtually a Dutch monopoly. A coarse kind of cinnamon, growing on the Malabar Coast, was still procurable; and the dearness of other kinds of spices, especially during the Anglo-Dutch War of 1652–54, led to some demand for cardamoms, obtainable in the same localities, and realising in England from 3*s.* 4*d.* to 5*s.* 9*d.* a pound. In general, however, the English found it hopeless to compete any longer with their Dutch rivals in the spice trade.

From about 1628 saltpetre figures prominently in the cargo lists of the homeward-bound vessels. The Dutch had for some time imported from the Coromandel Coast this necessary ingredient of gunpowder, and it may seem strange that the English were so slow in following their example. It must be remembered, however, that saltpetre was under strict Government control in England, and could neither be exported without permission nor sold to any but the King's powder-maker. Students of the time know the strange expedients resorted to in order to meet the evergrowing demand. The chief source of supply was from soil impregnated with nitrogenous animal matter; and the saltpetremen (as they were called) were empowered to enter upon any premises and dig up any earth, especially in stables, dovehouses, etc., which was suspected to contain the precious material. To such an extent was this interference carried, that in 1625 a royal proclamation was issued, forbidding the paving of stables, etc., or the hindrance of any saltpetreman from digging where he pleased. The quantity thus procured was, however, insufficient for the needs of the powdermakers, and supplies had to be imported from Danzig and other places. In February, 1624, the Commissioners of the Navy urged the East India Company to imitate the Dutch in bringing saltpetre from India; while at the close of the same year the Master of the Ordnance declared that the royal mills could no longer furnish the Company with powder, and that, if they wanted a regular supply, they must set up their own mills and bring in their own saltpetre. Thereupon instructions were sent out to the Surat factors to arrange for a supply, and a consignment, procured at Agra and Ahmadabad, was accordingly despatched to England. Meanwhile, the Company had (1626) obtained a licence to establish mills for the manufacture of gunpowder for their own use. This proved an unfortunate speculation. The first mills, set up at Egham, were ordered to be removed, as the noise disturbed the royal deer in Windsor Forest; whereupon the Company rented some mills at Chilworth, near Guildford—a locality ever since associated with the manufacture of munitions. The King's powdermaker complained loudly of this infringement of his patent, and for a time the concession to the Company was withdrawn. Finally, in February, 1637, they assigned their lease to Samuel Cordwell, who had secured a contract from the King in the previous November; and thus ended the Company's concern with the manufacture.

In India some difficulty had been experienced in procuring saltpetre, since its export was forbidden on account of its utility for warlike purposes.* Usually a bribe to the local officials removed all obstacles; but in March, 1628, the English and Dutch factors at Agra were imprisoned for a time for having bought and transported saltpetre without express permission. Ten years later, the Company, finding that at home they were forced to sell their stocks to the Government at prices much below the market rate, ordered that a preference should be given to other goods; and, in obedience to these instructions, the Surat factors first reduced, and then ceased their purchases. In 1643, however, they recommenced sending home a supply, pointing out that saltpetre was now cheap, and was moreover very useful as ballast, being shot loose into the vessel's hold.

The civil wars in Britain, followed by hostilities first with Holland and then with Spain, naturally produced a great demand for saltpetre. At the same time fresh sources of supply were being opened up in India. The development of trade with Rajapur and other ports on the Malabar Coast enabled the Company's servants

* In 1646 Prince Aurangzeb, then Viceroy of Gujarat, strictly prohibited the exportation of saltpetre, on the ground that the gunpowder made from it might conceivably be used against Mohammedans. The restraint was continued until his recall and the appointment of a less scrupulous successor.

to procure large quantities at a reasonable cost, though the expense and trouble of refining it at Surat induced them still to rely in the main upon purchases in Gujarat or at Agra. The same difficulty was felt upon the Coromandel Coast. The Madras factors wrote in 1652 that they could obtain an unlimited supply of saltpetre in Bengal, but must send it home unrefined, unless they could obtain from Surat some copper pans for boiling it, the earthenware pans used by the Indian refiners being troublesome and ineffective. They added that the Dutch shipped annually from Bengal nearly 2,000 tons, buying it raw at Patna and refining it at Pippli. Then, as now, saltpetre was abundant in Bihar, and a letter of December, 1650, says that the price at Patna was only one rupee per maund, though carriage and customs nearly doubled the cost by the time the saltpetre reached Hugli. As the Patna maund seems to have equalled about 78 lb., while at home saltpetre was fetching from £4 to £5 per hundredweight, it is evident that the commodity, though a bulky one to transport, yielded a handsome profit, after allowing for all expenses, including refining; and the numerous private ships that resorted to Bengal and the Malabar Coast during the period 1655-58 made their returns largely in this article. In July, 1657, Maurice Thomson and his associates, who were prominent in this traffic, declared that they had imported from Patna large quantities of saltpetre, much of which, after the needs of the English Government had been satisfied, they had exported to France, Sweden, Hamburg, Holland, and Italy, and that they hoped to make London the chief magazine in Europe for this branch of trade. In November, 1657, however, a note from the Company's servants at Surat states that on their side of India the exportation of saltpetre had been stopped owing to the outbreak of civil war, which ended in placing Aurangzeb on the imperial throne.

The remaining commodities imported by the Company may be dismissed more briefly. Lac—either in the form of stick-lac for dyeing, or of seed- and shell-lac for miscellaneous uses—was sent home from Surat at intervals during the greater part of the period; while supplies came also from the Coromandel Coast, obtained mostly from Bengal or Pegu. Sugar—both palm sugar from Gujarat and cane sugar from Bengal (procured partly by way of Agra)—was brought to England with fair regularity, though the Company attached little importance to this commodity, as evidenced by their placing it, in 1632 and again in 1650, among the goods which might be imported as private trade. The price realised in London was at first about £4 per hundredweight; it rose as high as £6 8*s*. in 1650, but declined to £3 or less in 1657, owing, possibly, to the competition of West Indian sugar. Other miscellaneous imports were ginger, borax, myrobalans, and various drugs, such as aloes (originally from Socotra), olibanum, benzoin, cassia, and spikenard. Cowries (obtained from the Maldives) were brought to England in 1647-50, but not in any great quantity; they were sold, it seems, for export to Africa. Coffee was a regular feature of the Company's trade in the East, their ships fetching it from Mokha for sale in India or Persia or at Basra; but although samples had been sent home in 1628 (apparently in response to a request), it was not until the end of 1657 that the Company ordered a supply for England; and the first time that it figured in their London sales was in August 1660.

In the foregoing list we miss several items which to-day figure prominently in the export trade of India. Tea or jute or hides we should not expect to find. Wheat was carried from Gujarat to Goa, and even to Bantam, for the use of the Europeans there; while biscuits made at Surat helped to provision the English ships for their long homeward voyage; but, of course, no one dreamt of carrying the raw material to England. Tobacco was another article which it would not have paid to send home, in view of the competition of Virginia. Rice figures at times in the Company's London sales; but it seems to have come from Bantam—not from India.

We have now to consider the commodities which the Company sent to India for sale there. Of these the most important was woollen cloth, the preparation of which, as already remarked, then constituted the chief industry of this country. It need scarcely be said that broadcloth, for which the equivalent of from 21*s*. to 28*s*. or more per yard was demanded in India, was not likely to be purchased for wear by ordinary people. As a letter from Surat (February, 1615) observed, the Indians could make three suits of clothes for the price of one yard of English cloth. But the Emperor and his nobles used this material to some extent for apparel, and still more for elephant trappings or saddles for horses; and, the custom once started, the officials of the imperial household could usually be induced to buy a considerable quantity on behalf of His Majesty. Bright colours

were chiefly in demand, especially reds, greens, and yellows. It is interesting to note that in December, 1639, the Surat factors reported that, whereas Jahangir had always preferred scarlet cloth, his more orthodox successor, Shah Jahan, would wear none but green. Throughout the period, though the demand varied considerably (partly owing to the competition of Dutch cloth, which was often superior to that brought by the English), broadcloth was a stock article of export, both to Surat and to the Coromandel Coast.

The other English products carried out were mainly lead, tin, and at first iron, though it was soon discovered that English iron stood no chance in competition with the cheaper Indian article. Lead—used mainly for making shot, but also for conversion into the red oxide for decorative purposes—was in constant demand in all parts of India. At Masulipatam in 1630 it was yielding 150 per cent. profit. The Surat demand was estimated in 1616 and again in 1628 at from twelve to thirteen thousand maunds per annum; while in 1639 the factors at that place declared that they could sell to the Governor for the Emperor's use almost any quantity that could be brought. The lead was chiefly in pigs or bars; but it came also as sheet lead, wrapped round the bales of broadcloth, and in that form it was stated to be yielding, in 1626, about as much profit as the broadcloth itself—a profit estimated, two years later, at 40 per cent. English tin found at times a market; but it was always exposed to competition from the tin of the Malay Peninsula, which commanded a much better price; and after a while the Company ceased to send any out. The considerable demand in India for copper was largely met by imports from Japan, brought by Dutch ships; and although the Company twice at least included a supply in their cargoes, it was found to be unprofitable and was given up accordingly. Quicksilver, on the other hand, was a favourite article of export from England to India, in spite of the trouble caused by leakage, and throughout our period considerable quantities were regularly shipped. It seems to have been mostly converted into vermilion (of which, however, a separate supply was often sent), and then used for decorating buildings, sacred and secular, or for toilet purposes. Both the Portuguese and the Dutch brought quicksilver to India from China, while some came also from Europe by the Red Sea route.

Another favourite item of commerce was coral, obtained originally from the Mediterranean, though here again there was competition on the part of that brought by the more direct Red Sea route. It was much in demand for personal adornment; while in the Deccan, we are told, it was used for burning with the dead. In 1626, and again in 1630, the profit made at Surat on this article was about 60 per cent.; at Goa in 1642 a consignment yielded 90 per cent. advance; and at Masulipatam in 1636 it was estimated that coral costing in England 14*s.* 6*d.* per pound would realise 100 pagodas per maund of 26 pounds, or over 170 per cent. In 1640 this commodity was declared to be the most profitable of all those sent to India. About 1647, however, a change set in, and prices went down, owing partly to large supplies brought by the Portuguese and the Dutch; though in 1659 we find the Company still purchasing a quantity for export to India. Coral beads were sent out as an experiment about 1645; but the prices were found to be too high, as the Indian workmen could make beads from imported coral at a much cheaper rate; while some of those received were unsaleable because they had crosses on them. Amber beads, by the way, were a profitable commodity between 1619 and 1629.

If it seems strange that Mediterranean coral could be carried to India with profit by such a roundabout route, it is stranger still to find that elephants' tusks, of which the main source was Africa, formed an important branch of the Company's early commerce, though a more natural route was that from Mozambique and other East African ports to Goa. The explanation seems to be that the supplies received by the latter channel were too irregular and too small to meet the very considerable demand in India for ivory for carving and inlay-work. However, suitable tusks were not always procurable in London at prices that would yield profit in India. From 1630 the export of this commodity virtually ceased until 1648, when a consignment sent out fetched a higher price than usual. In January, 1652, the Surat factors told their employers that ivory would always yield a profit.

Besides these ordinary items of merchandise, the Company sent out, especially in the early days, sword-blades, knives, mirrors, and many other articles for sale at the imperial court, including jewels, tapestry, satins, damasks, cloth of gold, and trinkets and curiosities of all sorts. The swords sold fairly well, though a regrettable preference seems to have been manifested for those made in Germany. The tapestry, manufactured mostly at the works started at Mortlake

in 1620 by Sir Francis Crane, was at first very popular at court; but in 1628 the factors reported against further consignments, as such hangings were now produced in India itself of a more suitable size. Some specimens sent out about ten years later were returned because no buyer could be found; while in 1652 the Surat factors declared that such articles were difficult to sell, especially if they had imagery on them. In that same year the English merchants were still endeavouring to recover from the gallant Raja Chhatarsal of Bundi the value of some tapestry which had, unfortunately, caught the fancy of his grandfather over twenty years before; and it is doubtful whether the full amount had been paid when the Raja fell, fighting for Dara against Aurangzeb, in 1658.

Sir Thomas Roe, during his embassy to India, urged strongly the advisability of sending out valuable jewels, of which he was convinced the Emperor and his nobles would buy up to £100,000 worth yearly. However, it was soon discovered that Jahangir, at all events, was a keen bargainer for such wares, and that any jewels refused by him or by his principal courtiers were difficult to dispose of, as no one cared to risk displeasure by purchasing them. In 1628 the factors advised that no more jewels of an ordinary character should be sent out, though large and rich pearls or rubies might sell to advantage. Apparently, however, the Company did not care to take any further risks in this direction, and so the trade in such rarities was left open to private speculators.

In spite of the Company's efforts to find suitable goods with which to fill their India-bound vessels, they could not avoid sending out a far greater value in coin or bullion as well, if return cargoes were to be provided. Statistics of these supplies of treasure are not often available; but we know that in the first twenty-four years of their trade the values of goods and money respectively sent out to all their Eastern settlements were in the proportion of about seven to fifteen; while in five later years the consignments to India itself showed a still greater disproportion—viz., about two to seven. As is well known, this constant export of the precious metals was the cause of many and bitter attacks upon the Company, and they would gladly have avoided it if they could; indeed signs are not wanting that for this reason they were content to continue sending out certain commodities so long as their proceeds would cover the bare cost of so doing. The usual form in which this treasure was carried was foreign silver coins, especially Spanish reals of eight (which were generally of a high standard of purity), though German or Dutch dollars, Florentine crowns, and silver ingots were also taken out. Whether coined or not, this silver had, of course, only a bullion value, since it had all to be turned into rupees at the Indian mints before it could be made available for the purchase of goods. The Company's charter permitted only the exportation of foreign silver; but in 1626, when, in consequence of the war with Spain, Spanish reals could not easily be procured, a licence was obtained from King Charles to export foreign gold. In the following year English gold or silver was allowed to be used, if necessary; while, later still, there were several grants for the exportation of foreign or English gold. On the Coromandel Coast, and in Southern India generally, gold was the standard currency; and even in Northern India that imported by the English proved in general more profitable than silver. In passing I may mention that in 1628 the Surat factors declared that, of the various kinds of gold coins sent out, there was "none that vends readier or yeilds more proffitt then 20*s*. peices English coyne." A little later, however, they reported that the demand for gold had fallen off, and advised that for the future only one-third, or at the most one-half, of the treasure sent out should be in that metal. The famine of 1630–32 depreciated still further the value of gold, since no one could afford to hoard it, and much that had been put away was now brought out and spent upon food. However, gold continued to be in demand on the Coromandel Coast; and in 1644 the Surat factors wrote that it was once again in favour in their parts of India, as the Dutch had not of late brought any from China. There was, indeed, no falling-off in the exportation from England down to the end of our period; and the acquisition by the East India Company of the Guinea Company's settlements in 1657 was prompted by a desire to utilise in India the gold dust procurable on the western side of Africa, and thus to reduce the amount of coin or bullion sent out from home.

Before concluding, something may fitly be said regarding the volume of the trade during the period under review. Unfortunately, the information available is very scanty, and such statistics as exist are of little use for our purpose, owing to the fact that they seldom apply to India alone. The outward cargoes included supplies for Persia, and sometimes for other countries as well; while those sent home from

Surat similarly comprised goods from Persia, and, in a few cases, some that had come from Bantam. The following figures, relating to the vessels despatched to England from Surat may, however, be given. The only ship that returned in 1616 carried goods to the value of £15,670; in 1619 the figure was £36,000; and in the following year £28,000, one ship being despatched in each case. In 1628 no less than seven vessels went home, with cargoes amounting to £193,440; while the ladings of the three ships of 1629 cost £51,150. Three more in 1639 carried home goods to the value of £109,570, and the cargoes of the two that returned in 1643 were invoiced at £58,770. Between 1648 and 1652 (both years included) the total for nine vessels was about £196,700, and in 1654 the lading of the "Welcome" cost £13,800. The figures, however, vary so widely, and the information is so defective, that no average can be struck. A safer guide is afforded by the tonnage of the ships sent home, as on that point the evidence is more complete. First, we distinguish a period of six years (1615–20), during which one vessel returns yearly with an average burden of 500 tons. Next come eleven years (1621–31) of increased trade, during which twenty-five ships go home, of an average of 590 tons, making 1,340 tons of merchandise per annum. Then, as a consequence of the Gujarat famine, the exports fall off, and from 1632 to 1638 only one vessel is despatched each year, with an average of 730 tons of goods. A spurt is made in 1639–40, five ships being despatched in the two years; but this effort spends itself, and the year 1641 is a blank. After this comes the Civil War in England, the increasing pressure of competition by private traders, and the troubles over the renewal of the charter. As a result, during the period 1642–58 we find only twenty-one of the Company's ships leaving Surat for England in the seventeen years, giving an average of 550 tons of merchandise per annum; but to these we may add seven sent home from the Coromandel Coast, raising the average of goods imported by the Company from India to nearly 700 tons per annum.* These figures, it must be remembered, include goods from Persia, etc. Moreover, they relate only to the Company's shipping, and the amount of Indian merchandise thus imported into England was largely increased, first by the vessels employed by Courteen's Association, and then by those of private traders during the period when the East India Company's charter was in abeyance.

Placed beside those of the present day, these figures may seem quite insignificant, as indeed all statistics of that period look when compared with those of an age when commerce has been immensely stimulated by the progress of invention and the resulting facilitation of intercourse between distant countries. At the same time it must be remembered that there were many reasons for the tardy development of trade between England and India. Harassed at home by an insufficiency of capital, by competition on the part of other traders, and by the troubles of the Civil War—impeded abroad by the hostility of the Portuguese and the Dutch, as also by the arbitrary and oppressive attitude assumed at times by the governments of the countries into which it sought to penetrate—the East India Company was beset with difficulties throughout the half century with which we are dealing; and, moreover, it had to serve a long apprenticeship, and experience many disappointments, before the possibilities of commerce between the two countries had been fully explored. At the close of the period, however, we leave the Company firmly established, both in India and at home, with a new charter, ample funds, and a monopoly secured by including in its ranks the most strenuous of its competitors. The result was seen in the great development that took place during the second half of the seventeenth century, and steadily continued until the trade of the Company was merged into that of the nation generally.

[The discussion on this paper will be published in the next number of the *Journal*.]

* For purposes of a rough comparison, it may be pointed out that a modern cargo liner may bring home at one time seven or eight thousand tons of merchandise.

SILVANUS THOMPSON MEMORIAL LECTURE.

At the meeting of the Röntgen Society held on April 9th, Professor Sir Ernest Rutherford delivered the first Silvanus Thompson Memorial Lecture. He dealt with the important advances in our knowledge of the constitution of matter, resulting from the discovery of X-rays in 1895. This marks the commencement of a new epoch in physical science, for in the attempts which were immediately made to ascertain the nature of the unknown radiation, attention was directed to the study of radiation in general, and new phenomena were soon encountered.

A general investigation of the cathode rays and of the nature of the discharge of electricity through gases led to the discovery of the "electron" and to the putting forward of the "ionisation theory" by Sir J. J. Thomson. Townsend followed up the

initial work by his theory of ionisation by collision, and O. W. Richardson investigated the emission of ions from incandescent solids. All this work was originally of academic interest solely, but within the last few years the practical applications have been shown to possess immense value. These include the production of detectors and amplifiers for wireless telegraphy, electrical rectifiers and oscillators by which radiotelephony across the Atlantic is now possible, and the Coolidge X-ray tube, which is destined to play an important part in radiology and in pure science. From the outset X-rays and the phenomena of phosphorescence were generally thought to be connected, and Becquerel, while in search of "invisible" or X-radiations from certain phosphorescent salts, discovered the radioactivity of uranium compounds. The brilliant researches of the Curies, by which this discovery was followed, resulted in the isolation of the radioactive elements, polonium and radium. Numerous other radioactive elements were brought to light, and the chaotic condition which ensued was not reduced to order until the introduction of the transformation theory by Sir E. Rutherford. Difficulties regarding the periodic classification were overcome by Soddy, who applied the term "isotope" to substances occupying the same place in the periodic table and which cannot be separated chemically, but whose atomic weights may differ slightly.

With regard to the study of X-rays themselves, no outstanding advances were made for some ten years after their discovery, when Barkla obtained evidence of the existence of "characteristic" radiations from experiments on secondary X-rays. The discovery led to the wave-theory of the X-rays, which was completely substantiated at later dates by the diffraction experiments of the Braggs, Moseley and Darwin. Barkla's characteristic rays are thus shown to be of the same nature as the rays yielding bright line spectra in the case of ordinary light. The diffraction experiments led to the employment of the X-rays for two classes of investigation—in the hands of Professor Bragg and his son, problems of crystal structure have been successfully attacked, while in the other direction the late Mr. Moseley has shown these phenomena to be a most powerful method of investigating the constitution of the elements. He showed that the critical property of an element was its atomic *number*, while its atomic weight was relatively of secondary importance. The important relationship between the frequency of the K or L series of characteristic rays and the atomic number of the element should be known as Moseley's law.

WAR-TIME ALLOTMENTS.

The *Journal of the Board of Agriculture* announces that during the third week of February land for over 7,000 new allotments was acquired or arranged for by twenty-five local authorities, acting on the advice of the Food Production Department, the acreage concerned being 499¾ acres. The average increase in the number of new allotments for the four preceding weeks laid out under the Cultivation of Lands Order by local authorities was at the rate of about 10,000 plots weekly. These figures are exclusive of the large number of new allotments provided by private arrangement.

Steps are being taken to secure land for cultivation by the workers at all munition factories. The idea is to utilise the produce of these allotments in munition canteens.

Schemes have been prepared to obviate waste of surplus produce raised by small cultivators. The essential part of these schemes, which, where necessary, will be modified to meet local requirements, is the establishment in each village of a collecting depot, to which all surpluses, however small, may be brought for packing and despatching to market. With the view of encouraging this desirable effort in co-operation, the Ministry of Food has undertaken to treat the potato crop raised by small cultivators in 1918 on an equal footing with the crops of potatoes grown on farms. Provided the small cultivators in each district combine, so that the produce can be bulked and transport saved, the State will purchase all the surplus main crop potatoes grown on holdings, no matter how slight. The experiment will be watched with much interest.

GENERAL NOTES.

Trinidad Oil Resources.—The Under-Secretary of State for the Colonies, Mr. Hewins, has informed the House of Commons that there are fourteen companies at present engaged in the oil industry in Trinidad. Three hundred and sixty-five wells have been sunk, and during November, 1917, to which the latest returns refer, 146 wells were actually being worked, and the quantity of crude oil produced amounted to upwards of 4,500,000 imperial gallons. Applications for further oil licences and leases receive the careful consideration of the Colonial Office and of the Trinidad Government, but by far the larger part of the presumed oilfield is already under licence or lease.

Treasury Notes.—Replying to a question in the House of Commons recently, the Chancellor of the Exchequer said the amount of currency notes outstanding at February 27th, 1918, was £218,409,536, against which £26,500,000 was held in gold. The total amount of Bank of England notes outstanding on July 29th, 1914, was £35,121,405, of which £29,706,350 were in circulation, and £35,415,055 in the reserve. There were no accurate statistics of the amount of gold in circulation at the outbreak of war, but the amount in the hands of the banks and the public, exclusive of gold held by banks of issue against their note issues, was estimated at about £120,000,000.

MEETINGS OF THE SOCIETY.

ORDINARY MEETINGS.

Wednesday afternoons, at 4.30 p.m. :—

APRIL 24.—SIR MAJOR ROBERT ARMSTRONG JONES, R.A.M.C., M.D., F.R.C.S., "Mental Effects of the War and their Lessons in Social and Medical Reconstruction." The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., will preside.

MAY 1.—GEORGE MARTINEAU, C.B., "Sugar from several Points of View." The RIGHT HON. LORD BALFOUR OF BURLEIGH, K.T., G.C.M.G., G.C.V.O., will preside.

MAY 8.—JOHN B. FARMER, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

MAY 15.—PERCY GROOM, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry."

MAY 29.—MARTIN O. FORSTER, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." SIR WILLIAM A. TILDEN, D.Sc., LL.D., F.R.S., will preside.

INDIAN SECTION.

Thursday afternoon, at 4.30 p.m. :—

MAY 30.—HON. SIR DINSHAW E. WACHA, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

COLONIAL SECTION.

Tuesday afternoon, at 4.30 p.m. :—

APRIL 30.—SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana." SIR EVERARD IM THURN, K.C.M.G., C.B., will preside.

CANTOR LECTURE.

Monday afternoon, at 4.30 p.m. :—

J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, "Military Explosives of To-day."

Syllabus.

LECTURE III.—APRIL 22.—High explosives used for shell filling—Methods of detonation—Initiators of detonation — Tests applied to explosives — Miscellaneous.

SPECIAL LECTURES.

A special course of three lectures on "The Freedom of the Sea" will be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m.

LECTURE I.—By GERARD FIENNES. Chairman, J. L. GARVIN.

Syllabus.

THE FREEDOM OF THE SEAS.

Freedom without Law. — The first maritime peoples—The Viking Age—Edward III. and the sovereignty of the seas—The Hansa—The Italian Republics in the Mediterranean.

Law without Freedom.—The discovery of the passage round the Cape of Good Hope and of America—The Bull of Alexander VI.—Henry VII.'s licence to the Cabots—Elizabeth's views—The English and Dutch—The war of Jenkins's Ear—The mercantile system—Berlin decrees—Orders in Council.

Law and Freedom.—Britain's work—Freedom "made in Germany."

LECTURE II. — By SIR FRANCIS TAYLOR PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905–12. Chairman, LORD SANDERSON, G.C.B., K.C.M.G.

Syllabus.

THE FREEDOM OF THE SEA IN WAR.

The breakdown of International Law due to unpractical theories—Effect of war on the Freedom of the Seas—Limitations of neutral commerce with the enemy—Rule of 1756—All interference with neutrals based on prevention of assistance to the enemy—"Free ships, free goods": the neutral doctrine essential to maintain the enemy's fleet—Foundation of a spurious Freedom of the Sea claimed by enemies and neutrals: consistent opposition to the doctrine by England—The armed neutralities—American War of Independence—Bonaparte's theories—Immunity of private property at sea—Declaration of Paris—Maintenance of English principles of belligerency essential to an effective League of Nations.

LECTURE III.—By JOHN LEYLAND. Chairman, The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S.

Syllabus.

THE GERMAN "FREEDOM OF THE SEAS."

Britain the great upholder of the Freedom of the Seas—The meaning of the term—How it was regarded by Grotius—How we came to be denounced as the "tyrants of the sea"—The attitude and policy of Napoleon—His claim to be the liberator from tyranny—The modern German claim a protest against British sea-power—An analysis of the claim—Its real meaning—The view held and expressed in the United States—The agreements and understandings with Prussia—President Wilson's declaration—How it is in conflict with the German claim—The need of a right understanding of the subject.

COBB LECTURES.

PROFESSOR HENRY R. PROCTER, D.Sc., F.I.C., Leather Industries Department, The University, Leeds, "Recent Developments of Leather Chemistry." Two Lectures.

May 13, 14. At 4.30 p.m.

London: Printed by WILLIAM CLOWES & SONS, LTD., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. BELL & SONS, LTD., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—April 19, 1918.

No. 3414. APRIL 26, 1918. Vol. LXVI.

JOURNAL OF THE ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

MEETINGS FOR THE ENSUING WEEK.

MONDAY, APRIL 29 ... Farmers' Club, at the Surveyors' Institution, 12, Great George-street, S.W., 4 p.m. Mr. J. C. Newsham, "The Future Position of Women in Agriculture."

TUESDAY, APRIL 30...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Colonial Section.) Sir Walter Egerton, "British Guiana."

Royal Institution, Albemarle-street, W., 3 p.m. Professor Arthur Keith, "Cave-Hunters." (Lecture III.)

WEDNESDAY, MAY 1...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. Mr. G. Martineau, "Sugar from Several Points of View."

Geological Society, Burlington House, W., 5.30 p.m.

Royal Institution, Albemarle-street, W., 5 p.m. Annual Meeting.

Public Analysts, Society of, at the Chemical Society, Burlington House, W., 5 p.m. 1. Mr. O. D. Roberts, "Factors affecting the Composition of Plant Ashes, with Special Reference to Tobacco." 2. Messrs. H. E. Annett and H. Singh, "The Effect of Codeine in hindering the Precipitation of Morphine by Ammonia from a Solution of its Lime Compound." 3. Messrs. J. L. Baker and H. F. E. Hulton, "Analysis of 'Cocoa Teas.'"

THURSDAY, MAY 2...ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 4.30 p.m. (Special Lecture.) Mr. G. Fiennes, "The Freedom of the Sea."

Aëronautical Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 8 p.m.

Royal Society, Burlington House, W., 4.30 p.m.

Linnean Society, Burlington House, W., 5 p.m. 1. Mr. G. M. Thomson, "On a new Fresh-water Shrimp (*Caridina*) from Fiji." 2. Dr. Marie Stopes, '*Bennettites Scottii*, sp. nov., a European Petrifaction with Foliage." 3. Dr. Marie Stopes, "A Survey of the Biological Aspect of the Constitution of Coal."

Chemical Society, Burlington House, W., 8 p.m.

Royal Institution, Albemarle-street, W., 3 p.m. Sir Isambard Owen, "Rheims Cathedral." (Lecture II.)

Metals, Institute of, at the Institution of Civil Engineers, Great George-street, S.W., 10.30 a.m. (Annual Meeting.) 1. Presidential Address by Mr. C. Eugène Schneider. 2. Selections from following papers: Report of the Blast Furnace Committee, "Practical Points affecting Yield and Efficiency of Blast Furnaces." Mr. G. D. Cochrane, "Importance of Coke Hardness." Dr. F. H. Hatch, "Economic Value of the Jurassic Iron Ores of Great Britain." Mr. T. C. Hutchinson, "Fuel Economy in Blast Furnaces." Mr. A. Lennox Leigh, "Economy in Gas Cleaning." Mr. Kenneth Chance, "Potash Recovery from Blast Furnaces." Mr. E. H. Lewis, "Manufacture of Portland Cement from Blast Furnace Slag." Dr. J. E. Stead, "Blast Furnace Bears." Dr. A. MacWilliam, "Technical Aspects of the Establishment of the Heavy Steel Industry in India, with Results of Some Researches connected therewith." Mr. B. Talbot, "Production of Sound Steel by lateral compression of the top portion of the Ingot." Mr. J. N. Kilby, "Steel Ingot Defects." Dr. J. E. Stead, "Notes on Inclusions in Steel and Ferrite lines." Mr. A. McCance, "Non-metallic Inclusions in Steel." Dr. W. Rosenhain and Mr. D. Hanson, "A Cause of Brittleness in Mild Steel Boiler Plates." Mr. E. F. Law, "Effect of Mass on Heat Treatment." Mr. J. H. Whiteley, "Effect of Cold Work on the Divorce of Pearlite." Mr. J. A. Van Den Broek, "Effect of Cold Working on the Elastic Properties of Steel." Dr. J. E. Stead, "Iron, Carbon and Phosphorus." Colonel N. Belaiew, "Damascene Steel." Dr. J. N Friend, "Protection of Iron with Paint against atmospheric Corrosion." Messrs. W. R. Schoeller and A. R. Powell, "Determination of Cobalt and Nickel in Cobalt Steel."

5 p.m. Annual May Lecture. The Hon. Sir Charles A. Parsons, "The Formation of Diamonds."

FRIDAY, MAY 3...Sociological Society, at the ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C., 5 p.m.

Royal Institution, Albemarle-street, W. 5.30 p.m. Sir George Greenhill, "The Spinning Top in Harness."

Metals, Institute of, at the Institution of Civil Engineers, Great George-street, S.W., 10 a.m. (Annual Meeting continued.)

Philological Society, University College, W.C., 8 p.m. Anniversary Meeting. Mr. H. Palmer, "The Ergonics of Japanese."

SATURDAY, MAY 4...Royal Institution, Albemarle-street, W., 3 p.m. Professor H. F. Newall, "Modern Investigation of the Sun's Surface." (Lecture II.)

Journal of the Royal Society of Arts.

No. 3,414. VOL. LXVI.

FRIDAY, APRIL 26, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

NOTICES.

NEXT WEEK.

TUESDAY, APRIL 30th, at 4.30 p.m. (Colonial Section.) SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana." SIR EVERARD IM THURN, K.C.M.G., C.B., will preside.

WEDNESDAY, MAY 1st, at 4.30 p.m. (Ordinary Meeting.) A paper by GEORGE MARTINEAU, C.B., on "Sugar from Several Points of View," will be read by EDWARD R. DAVSON, President of the Associated West Indian Chambers of Commerce. The RIGHT HON. LORD BALFOUR OF BURLEIGH, K.T., G.C.M.G., G.C.V.O., will preside.

THURSDAY, MAY 2nd, at 4.30 p.m. (Special Course.) GERALD FIENNES, "The Freedom of the Seas." J. L. GARVIN will preside. (Lecture I.)

Further particulars of the Society's meetings will be found at the end of this number.

CANTOR LECTURE.

On Monday afternoon, April 22nd, Mr. J. YOUNG, O.B.E., A.R.C.S., F.C.S., Chief Instructor in Science, Royal Military Academy, Woolwich, delivered the third and final lecture of his course on "Military Explosives of To-day."

On the motion of the CHAIRMAN (Major-General Sir Desmond D. T. O'Callaghan, R.A., K.C.V.O.), a vote of thanks was accorded to Mr. Young for his interesting course.

The lectures will be published in the *Journal* during the summer recess.

EIGHTEENTH ORDINARY MEETING.

Wednesday afternoon, April 24th; The RIGHT HON. LORD SYDENHAM, G.C.M.G., G.C.I.E., G.B.E., F.R.S., in the chair. A paper on "Mental Effects of the War and their Lessons in Social and Medical Reconstruction" was read by MAJOR SIR ROBERT ARMSTRONG-JONES, M.D., F.R.C.S., R.A.M.C.

The paper and discussion will be published in a subsequent number of the *Journal.*

EXAMINATIONS.

The entries for the Society's Examinations this year number 30,720. Of these, 10,828 were received for the examinations held in March, and 19,892 for those commencing on May 6th.

These entries show an increase of 4,814 over those of 1917, when 25,906 entries were received.

In addition to the above, entries have been received from interned prisoners of war at Chateau d'Oex and Mürren, Switzerland, and from the internment camp at Groningen, in Holland.

PROCEEDINGS OF THE SOCIETY.

FIFTEENTH ORDINARY MEETING.

Wednesday, March 20th, 1918; SIR HENRY TRUEMAN WOOD, M.A., Member of the Council of the Society, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Heine, William M., Connecticut, U.S.A.
Malcolm, George William, London.
Stobie, Victor, Gosforth.
Strachan, Robert Price, Bristol.
Weir, John Cunningham, London.

The following candidates were balloted for and duly elected Fellows of the Society:—

Anstruther, George Elliot, London.
Crabb, Thomas, M.I.Mar.E., A.M.I.Mech.E., Bengal, India.
Hepburn, Andrew, Horley.
Letcher, William Whitburn, London.
Mannell, John, London.
Mitchell, Ernest J., London.
Murray, Alexander Robertson, Calcutta.
Pardoe-Thomas, Bertie, J.P., Newport, Monmouth.
Pocock, George, London.
Poupart, John, Walton-on-Thames.
Powles, George Everett, Leeds.

Rama, Varma Raja, His Highness, F.R.Hist.S., Malabar, S. India.

Robertson, Walter Henry Antonio, Bedford.

Stewart, John, London.

Tonkin, Wilfrid Wiseman, Lic.R.I.B.A., Potchefstroom, South Africa.

Ullyott, E., Leeds.

Walter, Francis Henry, Rio de Janeiro, Brazil.

The paper read was—

THE FOOD SITUATION IN GERMANY.

By Percy Shuttlewood.

The food situation in Germany is so vital in its bearing on the war that a dispassionate investigation of the existing conditions is of interest. A survey of available statements and statistics leads to a general conclusion that the immediate situation in the countries of the Central Powers is grave enough to be termed critical. It may be laid down as a general proposition that Germany is able normally to produce from her own resources a bare sufficiency of food to keep her people alive. It is abundantly clear that a bare sufficiency is inadequate to maintain a nation's highest efficiency. The cumulative force of the food shortage, the lack of variety of food, the difficulties of transport, and the inequalities of distribution are exercising a continuous drag on the power and will of the German people to carry on.

After three years' experience of a rationing system and one year of an official Food Controller, Germany still finds it impossible to come within measurable distance of solving her problem of distribution.

The results of the British blockade can best be judged from the effect which the blockade has produced on the larger industrial and commercial towns in Germany. Every country has certain agricultural districts which are more or less self-supporting, but by cutting off supplies from outside it is possible to reduce a country to the position of having to fall back upon its own supplies. As far back as November 26th, 1917, mass meetings, summoned by the Federation of Trade Unions, were held in seven large halls in Berlin to bring pressure to bear on the authorities with a view of improving the food ration of the Berlin working-classes. A resolution was passed at all these meetings demanding more energetic opposition to illicit trading, a uniform supply for the whole economic area of Greater Berlin, and an increase of the potato ration to 10 lb. per head per week. In spite of all their resolutions, however, it appears that the rations of meat, bread, potatoes, and sugar remained unchanged for the area of Greater Berlin in December and January. Although the potato ration was fixed at 7 lb. per week, only a 6 lb. ration was distributed during the week beginning December 31st.

The fats ration was reduced in December to 2·5 oz. A ration of one egg per week was fixed for the period December 17th to 31st.

Apparently the small rural communes round Berlin are as hard hit as any place in Germany.

Berlin is not the only town in Germany which is feeling the pinch of the British blockade, as evidenced by the fact that in 1917, 40,000 children were sent from Hamburg schools into the country in order to recuperate. According to a merchant who has recently left Hamburg, after a long stay in that town, one could obtain almost anything there by buying secretly and paying fabulous prices. As an instance he cites the case of a ham weighing 15 lb. purchased for £47 10*s*.

It is obvious, however, that everybody in Hamburg cannot afford these prices. Eggs, fats, and butter are extremely scarce, and the soup kitchens are getting very bad. People in Hamburg are very weak, especially the women and children, who are feeling it badly. Naturally there is discontent when people see that the rich are able to obtain food at prices which are beyond the reach of the poorer classes, and it is stated that the people of Hamburg are frankly speaking of revolution after the war.

Illicit trading is gradually assuming dimensions which justify the fear that the whole public supply of food in Germany may be undermined. Private smuggling between consumer and producer is the natural reaction against the orders of the rationing system as operated in Germany. Little attention was paid to it at first, and as it developed it was opposed in an inadequate fashion because there was no definite procedure and too many extenuating circumstances were taken into account. The District Commissioner who could allow the city man who had rented a shoot to take butter and lard with him, could not proceed with energy against Sunday excursionists.

The municipal authorities were not displeased, in their turn, to see this increase in the supplies of their citizens. It is asserted that in the early spring of 1917 absolute distress was only avoided in Frankfort by openly dealing in illicit trading, which brought potatoes previously hidden from the authorities into Frankfort by the hundred-

weight. This illicit trading, moreover, is not by any means confined to well-to-do circles, but everyone uses his connection with the war to increase his meagre ration from one source or another.

Frankfort is the town where the egg ration works out at one egg per head for four weeks. The fat ration is 1·7 oz. per week; and the meat ration 7 oz. per week.

Hanover, however, promises to be even worse off. The weekly ration of butter has been steadily decreasing. In February, 1918, the butter consignments were so small that the magistracy announced that, in place of butter, 2·1 oz. of the best edible fat, a very imperfect substitute, would be given.

The proceedings of the Chamber of Agriculture in Hanover provided a fairly good insight into the local conditions. Apparently 1917 has been a bad year for agriculture. The drought, which lasted until June, played havoc with the oat crops, and the autumn-sown crops were hardly of medium standard. Lack of manure, shortage of labour, and insufficiently nourished teams, have all been unfavourable to the harvests. Encroachments made on cattle stocks have given serious cause for anxiety as to the future of breeding. Pig stocks have been ruined, the number of pigs having decreased from 25,000,000 to 5,000,000 since the beginning of the war.

Of course, conditions such as these are bound to affect the large towns. There is an epidemic of "hunger typhus" in Hanover as well as in South Germany.

In Bentheim, on the Dutch frontier, they have one egg weekly and 2·975 oz. of butcher's meat. Coffee, tea, cocoa, and rice are unobtainable, except what the smugglers bring and sell at incredible prices. One half-pound of tea costs £1 5*s*. A protest was recently forwarded to the Ministry of Food by the Hirsch-Duncker, the Union of Engineers and Metal Workers. The metal workers are engaged in munition-making, and are visibly collapsing through physical strain and inadequate food. Groats, barley, peas, fat, etc., are supplied to them in very small quantities, and sometimes not at all. The only thing that the workers have to depend on is potatoes. The ration of 7 lb. per week is quite inadequate, and their future capacity is seriously threatened.

In every part of Germany the authorities are confronted with the same problem of illicit trading, and this is one of the main grievances under which the German workman is labouring to-day. He is tired of the war; he is expecting a certain amount of food and he does not get it; he sees others who appear to have no difficulty in obtaining in some mysterious way commodities which he has to go without. It does not require a very great knowledge of psychology to enable one to form a fairly accurate idea of the German working-man's mind under such conditions.

A Dutch traveller, writing to friends abroad, says: "I saw, during my holidays, some German girls, aged sixteen years, who came to us to be fed. They had gruesomely thin legs and faces, wasted to skin and bone. They were so weak that they could not retain any kind of food. The people showed us a letter from a German boy about ten years of age, who, four weeks after he had returned to Germany, wrote: 'The 12 lb. I gained I have already lost—quick, wasn't it?'

"I do not understand how they copy in the papers such a report as this: 'Even in the fourth year of the war the food provisioning gives us no anxiety.'"

The Germans are reading such news, and yet they feel they are starving.

The following is an extract from a letter which was written in Bremen: "We have not had any potatoes for six weeks, and we only get 5 lb. of bread and 1 lb. meat per week, and every fortnight or three weeks 3·5 oz. vermicelli or barley, not enough to live upon, and too much to starve to death. Without our supply of milk we should have all died." The writer also complains of the unduly hard lot of the working-classes as compared with rich persons.

The people are suffering, but they are buoyed up by hopes and promises from the German authorities. The majority of the people want peace, but they dare not express their opinions openly for fear of the consequences.

The writer of the letter to which I refer does not think that there is the least fear of any revolution, as the masses are crushed under the heel of the military authorities.

A writer from Spain says the Germans have brought food rationing to a "scientific fine art," and it is marvellous what they have been able to do, making one thing replace another, and doling things out in such quantities as are just enough to keep the people from starving to death. When people are prepared to pay over £45 for a single ham, one can understand that hosts of opportunities will spring up in order to do business under such conditions. For weeks the authorities have been bullying the wretched municipalities without taking any steps to

remove the cause of the prevailing abuses. Recently the municipal authorities purchased a number of truck-loads of white cabbage at a price above the maximum 11*s.* per cwt. The firm of Krupp pay 17*s.* per cwt. Nothing is known of any action against Krupp.

The Ministry of War is endeavouring to profit by such transactions. The War Department was offered ham and sausages at 14*s.* per lb., which were bought up at once.

At a meeting of the Imperial Fruit and Vegetable Offices, attended by representatives of the Berlin food committees, the representatives actually stated that the observance of maximum prices at present could not be thought of, and stopped all debate on the point. On one hand the legal authorities are announcing their intention of prosecuting all offenders against maximum prices legislation, and, on the other hand, the Imperial authorities are deciding that for the time being, at any rate, maximum prices may be exceeded.

A German newspaper's comment is: "The nation will certainly conclude that there is no serious desire to improve matters. The people ask for bread and are being played with."

It is true that the authorities are taking timid steps towards checking the illegalities of industrial firms. The War Food Bureau recently discussed the situation with the managers of industrial undertakings, and issued a warning against publicly controlled foodstuffs being obtained through illicit trade. The defiance of regulations by private traders goes on unchecked. Pigs have been slaughtered at night without licence, and the meat sold, without inspection for trichina, at 5 marks (5*s.*) per lb., the maximum price being about 1·80 marks (1*s.* 9½*d.*) per lb. Apparently a buyer for the municipality of Allenstein, after giving up his butcher's business, went on for about twenty weeks with secret slaughterings of altogether about forty to fifty bullocks and ten to fifteen calves and sheep.

Pigs, calves, and sheep have been bought up without licences, secretly slaughtered, and resold to hotels. According to the *Münchener Post*, January 25th, 1918, the Munich railway station for Berlin was watched by detectives, and lately two suspiciously heavy boxes were opened and found to contain quantities of food and an invoice.

Butter was priced at 13 marks (13*s.*) per lb., and a ham for 75 marks (£3 15*s.*) The ham, in comparison with the other hams, appears to have been a bargain. A restaurant near the station has been enticing farmers to bring lard, butter, etc., into town by offering them up to 15 marks (15*s.*) per lb.

Munich is not, however, the only place where the station is watched. On any morning one can see crowds waiting in the cold and in the fog on the suburban railway platform of a Berlin station for the train to start. Long rows of hungry creatures are there—men, women, and children—all with baskets and sacks in their hands. Their baskets and sacks are laden with potatoes when they return twelve hours later, but the potatoes are confiscated by the police almost before they get out of the train.

A traveller in Holland who has recently left Germany, describes a scene at a station in Western Germany. A crowd of people who had been buying vegetables from local farmers found that the train which was to take them home was already full up. They smashed the carriage windows and almost wrecked the train in their endeavour to get seats.

Apparently the railway conditions in Germany are getting worse and worse. Soldiers who come from the front on leave state that the conditions in Germany are worse than in the occupied parts of France and Belgium. A prisoner of war who escaped from Germany last December, after having been more than three years in various camps, states: "At first they seemed to have plenty of food, and to be very confident about things, now they are very downhearted and they do not seem to care very much which way the war goes as long as it comes to an end soon. At one time they used to read the papers a lot, but now they do not seem to worry about it. They would say that the war was all for the Kaiser's pocket and the poor man would get nothing from it."

Bread often has bits of wood in it, and the British prisoners used to give their bread to the Russian prisoners who were in a barrack close by. Their civilian sentry used to say it was worse for the women and children as they had no milk.

The German authorities are powerless to suppress illegal trade, and consequently, in spite of careful calculations, there is not enough food left to distribute according to the scale of distribution. The Food Controller reckons on a certain supply and arranges a distribution; but meanwhile transactions are going on concerning which he knows little or nothing, the net result being that the supply does not come up to his expectations, and the distribution suffers accordingly. The people, therefore, do

not get what they have been promised; they have, moreover, to pay a price above that which has been fixed by Government. Their grievance is a perfectly legitimate one, and nothing saps the patriotism of a nation more than a series of justified grievances. Probably it is this grievance which has contributed to war weariness on the part of the masses in Germany more than anything else. It is foolish, however, to conclude hastily that because the German people are hungry and war weary therefore they are ready to revolt.

An announcement appeared on October 9th, 1917, that the War Food Ministry had been reorganised on a new basis. This Ministry will consist of a Minister, two under secretaries, and nine other members. The Minister will conduct the business and will represent the Ministry outside, and will be responsible for the fulfilment of the duties entrusted to it. He will decide important questions only after consultation with the advisory committee, at whose meetings he will preside.

The system of rationing by card appears to have been very complicated, and, in order to guard against forgeries, the Food Supply Bureau has always used paper with a watermark. The control starts with the paper, which is supplied by the factory direct to the Food Supply Bureau. The paper is manufactured and counted under official supervision and stored in the cellars of the Food Supply Bureau. It stands to reason that precautionary measures have been taken to prevent fraud. The sheets of paper are counted off as wanted and delivered to the printers, who print under constant supervision. During the dinner-hour the machines are put out of action and sealed. Nine printing establishments are employed with 160 honorary supervisors.

The cards, when printed, are packed in parcels, then sealed, and are sent to the distribution offices in military motor-lorries under the most careful control. The parcels are locked up in schools in separate boxes, where they remain only one, or at most two, nights. Then they are sent to the commissions, still under guard, and are then put into the envelopes and delivered by school children. Also in the schools precautions have been taken against fraud and theft. When the periods of the cards have expired the distribution offices have to make up their accounts. Any surplus, never very extensive, is returned to the Food Supply Bureau. Formerly the surplus was burnt; now, on account of the scarcity of paper, the waste-paper is pulped under strict supervision. The Food Supply Bureau gives the assurance, relying on its accurate book-keeping, that the number of cards distributed now corresponds with the number of the census. The enormous business transaction involved is illustrated by the fact that for bread cards alone 50,000 to 60,000 sheets of paper are used every fortnight. And if one remembers that 130 different cards are in question, and that every card has to be booked, a good idea is gained of the daily amount of work.

The most difficult part is the distribution of cards to men on leave at the chief railway station. Five thousand men on leave have to be supplied daily. The different periods of leave, which make it necessary for cards of the old and new distribution periods to be issued at the same time, and the necessity for taking into account the meat days, combine to render the issue very difficult. The cards are now handed out in envelopes; for seven days' leave (five meat days) these contain vouchers for 2,000 grammes of bread and flour, ten meat vouchers (each one valid for a tenth of a current weekly supply), fourteen potato vouchers, seven milk vouchers, seven sugar vouchers, one fat, one cheese, and one groceries voucher, and an egg card.

As soon as an order is issued, three-fourths of the population seek how they may evade it. They have lost faith in official promises, and the fear of starvation has them in its grip.

It is stated that in the country all possible provisions can be obtained if one has other commodities—*e.g.* sugar, rice, soap, petroleum, etc., to exchange. The shopkeepers in the towns are also good hands at this system. Though they may have nothing on view in the shop there is always something in the background which they will exchange for other goods on favourable terms.

A complicated and special series of coloured cards has become necessary in order to control milk distribution. Brown cards are used for skim milk issued to women and girls, black cards for skim milk to men and boys, and red cards for children's whole milk rations. There appear to be other sub-divisions to include invalids and old persons.

Further complications have been introduced in certain districts: for example, in Hanover milk salesmen have been directed to favour families with children over six years of age, and for this purpose may issue *special* cards or even supply milk on ordinary *food* cards.

The constant variation in supplies of any foodstuff constitutes another difficulty, necessitating continual changes in orders. For instance, in Hamburg recently it was ordered that 1 lb. of white cabbage should be supplied on each card contrary to the procedure of the previous week, when cabbage was supplied on several household cards only.

The problem of arranging for persons who take their meals in restaurants has been the occasion of much controversy. In Austria special restaurants have been introduced covering the whole meal. The official meal check must be handed to the restaurant proprietor, and persons applying for meal checks must have a written declaration that they regularly take their meals away from home.

It is not clear how far such persons become entitled to any ordinary food cards, but the system seems to be open to abuse. The usual method in Germany is for restaurant diners to produce their ordinary cards at a meal and for coupons to be detached covering the rationed dishes. There are always a number of dishes not requiring cards. It is also possible to buy books of restaurant coupons, ordinary food tickets being surrendered in return—*e.g.* one bread ticket for thirty restaurant bread coupons. There has been much evasion of the regulations in restaurants, and a great tendency for unrationed foods to be supplied only at exorbitant prices.

As regards mass feeding in public kitchens, the card system seems to have partially broken down. In 276 establishments, of which sixty-nine were public war kitchens, the demand for surrender of food tickets has been abandoned. These establishments are almost entirely in the smaller communes.

In the other towns surrender of tickets is made a condition in order not to interfere with the equitable distribution of supplies over the whole population.

It is of interest to note that a system of supplying separate courses has been generally given up in favour of the one-course meal.

Towards the end of August, 1917, in Altona and Hamburg it was found advisable to modify the organisation of all kitchens in order to make the food more nourishing and varied. A report which reads like an official order, alludes to Imperial food cards, the use of which in connection with war kitchens appears to require a considerable amount of adjustment:—

"From August 20th only such people can order food from the Altona war kitchens as have in the preceding week got for themselves vouchers entitling them to an allotment of food on presentation, and involving cancellation of a corresponding amount on the imperial meat, potato, and food cards.

"If a kilo of food per day is ordered for the duration of a week, half of the weekly amount of potatoes, half of the ration in farinaceous foods, and six-tenths of the weekly meat ration must be cancelled. Those who fetch the food may not receive more than 1 kilo per head daily. Only those who consume the food in the kitchen may eat 1½ to 2 kilos there daily. When these order 1½ kilo of food for the week, five-eighths of their potato ration will be cancelled, besides the above-mentioned amounts of farinaceous food and meat. When they order 2 kilos of war kitchen food daily for the week, six-eighths of the weekly potato supply will be cancelled, besides the above-mentioned amounts of meat and food. The vouchers are available only for the kitchen marked on them and in the week for which they are issued.

"Inhabitants of Altona who wish to order food from a war kitchen must obtain their vouchers at their proper bread commission, and must then exchange them at the Hamburg kitchen from which they want to order the food for the cards there current."

An official inquiry took place as to the extent to which the various people's and middle-class kitchens make the amount of food supplied by them dependent on the surrender of meat, potato, fat, and other food tickets. Replies were received from one hundred municipalities, and these show great difference both as to the manner and the extent of deductions made.

In most towns tickets must be surrendered for meat and potatoes, but only a minority demand fat, pulse, flour, or other food tickets. In a few towns the people's kitchens do not as yet require tickets; some other towns require them only for potatoes.

As to meat tickets, there is evidence of a general desire to meet the wishes of the participants as far as possible, and to leave them a larger or smaller portion of the ticket at disposal for use elsewhere. The extent to which surrender of the tickets is required depends in the various people's kitchens on the greater or less frequency with which meat dishes are provided. Frequently the rule obtains that the surrender of only half the meat tickets is required. The majority of towns have introduced day tickets, but others have weekly and monthly tickets, and a few even demand the meat and other tickets for three months in advance.

With regard to the U-boat campaign, the secret history of this venture is interesting. Early in 1916 ten financial and industrial experts were questioned as to the advisability of Germany pursuing an unrestricted submarine campaign. They all agreed that six months of ruthless U-boat warfare would compel England to sue for peace. Had these men foreseen for a moment that the war would go on in spite of all, it is hard to conceive that they would have advocated a policy so suicidal to their own interests.

"Die Hilfe" says the authorities were deceived on very substantial points regarding its effects. It is not much consolation to a hungry man to be told that his countrymen have just succeeded in destroying vast quantities of food.

Herr Segitz, at the sitting of the Bavarian Diet in January of this year, referred to the U-boat campaign. He said: "We are confronted with world famine, yet we are rejoicing every day when ships with provisions are sunk because we hope it will force England to surrender. But after the war ships will be lacking to bring us corn."

It is perfectly true that efficiency rather than humanity is the German ideal. Her food organisation is certainly nothing to admire. She still has her queues, and is not likely to get rid of them.

The press of this country and speakers generally often draw comparisons of the relative English and German rations.

In no part of Germany is the full ration to be obtained with any degree of regularity.

The statistics to which so much importance is attached in this country are not accepted by the German Food Controller himself, who has stated:—

"Our potato harvests can be designated as satisfactory and in some parts good. Since the statistics appear to have proved misleading a revision is ordered to take place immediately."

Not long ago the town council of Neukoln (Greater Berlin) submitted a memorial to the President of the War Food Bureau. It was rigidly repressed by the authorities. This document accuses those who handle the country's food of partiality, and demands drastic reforms which will secure uniform distribution.

Recently captured documents included a letter from a certain Government official, which showed clearly that it is the middle and lower classes in Germany that are suffering severely. The mass of Government officials, bureaucrats, influential junkers—in fact, all who hold office in the Government itself—have little difficulty in procuring supplies. It is an ugly picture of Prussian bureaucracy at its worst.

Last year in Prussia alone there were over 40,000 prosecutions for food hoarding and profiteering. In some towns the bread cards had to be called in, as so many people were forging them.

A British officer, recently returned from Germany, states that during the last two years there has been a very marked difference in the appearance of the inhabitants. The men are thinner; the women and children are white and pinched. Last winter the death-rate in certain towns was exceptionally high. Epidemics among the very young have been common, generally of an intestinal nature due to the use of substitute food.

German soldiers in hospital state that deaths from disease have increased enormously in the army. With regard to food issued to the army, evidence all points to the fact that both in quantity and in quality the rations are rapidly deteriorating. British doctors who examine prisoners of war as they are brought in agree that the physique of the German soldier is not what it used to be. They are unanimous in tracing the cause to the lack of proper nourishment.

The German Food Controller has stated in the Prussian House of Deputies that the fourth year of war would impose many restrictions. Bread and potatoes, he said, will form the mainstay of the food supplies. Amid a mighty sounding of trumpets the German professors devised a process for extracting nitrogen from the air. As a makeshift this has its uses, but only as a makeshift. The nutritive values of the foods thus produced are greatly inferior, on the showing of their own scientists, to pre-war foods. They grind acorns and call the result coffee. Sawdust is used as a flour stretcher. Von Waldow's rationing system is a failure. The Prussian system breaks down, as Von Waldow ruefully confesses, when applied to producers, profiteers, and the distributing agencies. The farmers make dishonest returns. The profiteering middlemen pile up their profits and snap their fingers at the State.

The German authorities are powerless to control the distributors. They are powerless to organise the transport of food. The military demands on transport take precedence. The lack of grease and the colossal deterioration of rolling-stock of the Empire are vital factors.

Little wonder Von Waldow's rationing system has proved a failure. The people asked for bread and he gave them coupons. They stood long hours in queues and came away empty-handed. He failed because there was too little food and he was powerless to control the supplies.

Hans Vorst has discussed the dangers from a German point of view of overrating the economic consequences of peace with Russia, and points out that at all times Russian exports have only been possible to the detriment of the masses. Owing to the shortage of agricultural labour both the area under cultivation and the yield has during the period of the war decreased year by year. At present it is doubtful if the crops, even with efficient organisation, are sufficient to meet the needs of the Russian people.

It is possible that there may exist some surplus holdings or land held by the peasants themselves. Neither the Imperial nor the Provincial Governments of Russia, however, succeeded in raising the hidden treasures. One may therefore doubt their magnitude. When the Kerensky Government, in September, 1917, doubled the maximum prices the peasants were still reluctant to sell. If Hans Vorst is right, it is patent that the Central Powers have little to hope from Russia. Vorst bases his arguments on solid facts.

The fabric built up by the Prussian system has not yet been destroyed. The will to victory is impaired. It is maintained by coercion and lying promises, by threats, by dramatic achievements. For the rulers of the German Empire everything is at stake. They will leave no stone unturned to prevent the Empire from collapsing under the pressure of hunger. Though red ruin and disease are prophesied for the people at large, those who will suffer least are those who still guide the helm of State. Although Germany's condition is critical it would be premature, and in the highest degree imprudent, to assume her early collapse.

DISCUSSION.

The Chairman (Sir Henry Trueman Wood), in opening the discussion, said he believed an eminent philosopher once divided mankind into two classes—the people who ate too much and the people who did not get enough to eat. There was no doubt that in the past a very large number of Germans belonged to the first class, but the great majority of them had now been brought into the second class. It was satisfactory to have confirmed in the paper the information given by the various correspondents who had sent letters to the *Times* and other papers depicting the condition of Germany. To his mind it was degrading that the people of this country should be compelled to gloat over the misfortunes of those who, after all, were their fellow-creatures, but that was not their fault; the Germans had brought it upon themselves by their insensate plunge into war. The author had avoided drawing any comparisons between the food situation in this country and the situation in Germany, but there were several very useful lessons that might be obtained by such a comparison. The very moderate restrictions that the people of this country were now having to submit to were absolutely nothing compared with those which the Germans had been enduring for certainly three years; but it must be remembered that the time might very likely come when we should have to support hardships a great deal more severe than the present ones, and we must be prepared to bear them when that time came. A question that must arise in the mind of everyone was, What was to be the ultimate result of the starvation of Germany? Mr. Gerard, in the observations which he had recently published—observations notable for their shrewdness and their evident truth—stated that we could never look for any revolution in Germany, whatever might happen; and that was probably correct. If the people of England or America had been treated as the Germans were, there would very soon be revolutions, because those countries were democracies. It was the old story of a lot of loose twigs and a bundle of sticks—a democracy might be said to consist of people tied up into various bundles, who were in a position to say what they wanted and to see that they obtained it; whereas the German nation was composed of slaves who had no power whatever of making their will known; they were trodden down and had no organisation, and were not even allowed to express their opinions. The economic condition of Germany must have its effect, however, in the long run. People could not go on starving; they could not be infested by disease, as it was known the Germans were, and they could not be reduced to the lowest possible moral condition, so that crime was rampant in Berlin and in all the other German cities, and yet go on putting up a good fight. That might therefore be a cause for hope on the part of this country; there would not be a revolution in Germany, but there would be some sort of decay which eventually would bring about the defeat of the Germans. There was one point at the end of the paper which had rather puzzled him, where the author spoke of the production of nitrogen from the atmosphere. So far as his information went, the principal development of the manufacture of atmospheric nitrogen in Germany had been the application of steam-power to its production instead of water-power, a change only justified by the increased value of the product. The nitrates thus obtained were used in the production of explosives, as well as for fertilisers. He did not know that they had been utilised for

the manufacture of foodstuffs, and any information on this point would be interesting.*

ALDERMAN G. CLEMENT, speaking as a member of a food control committee, said that his committee had a great many difficulties to contend with. Several members felt that less corn should be used for brewing purposes, because everyone must recognise that the question of bread should come before beer. Undoubtedly a considerable quantity of good wholesome grain was being used at the present time for brewing, and those in authority might do well if they reduced the amount. The local food committees were told that from 30 to 35 lb. of potatoes should be used to every sack of flour in making bread, but difficulties had arisen in his district with regard to preparing the potatoes for that purpose. There was an abundant supply, but the bakers were disinclined to use the potatoes unless they were supplied with machinery for preparing them, and it was very difficult to obtain that machinery. One baker resident in his district had been promised a machine some time ago; it had been suggested that the Government should expedite the delivery of the machine, which would then be placed at the public baths, so that all the bakers in the neighbourhood could have potatoes prepared for them there. Unless some means of that kind were adopted it was very probable that the supplies of corn would not last out till the next harvest. There should also be some relaxation of the order issued by the Food Control Department to the effect that sugar for making jam could only be obtained by those who grew their own fruit. His committee thought that sugar for that purpose should be supplied to all who had got the fruit, whether they had grown it themselves, or purchased it, or had it given to them, provided they could satisfy the local food committee as to their intentions.

MR. W. E. OAKDEN wished to know whether the author could say what percentage of the total food supplies of Germany were produced in Germany before the war and at the present time, and also if he could give any idea of the date at which he considered the Allies' blockade was effective in preventing imports into Germany.

MR. W. J. BRAITHWAITE said that the German people loved the preparation of statistics, and the result was that the figures showing the number of prosecutions, the want of obedience to the law, and so forth, were accumulated in a way that was absolutely incredible to people in this country. He had twice had experience of official investigations in Germany, and on both occasions he had been very much surprised at the number of prosecutions, and the apparently horrible lawlessness of the population. He therefore wanted to introduce a note of caution on that subject. He did not believe the Germans were a lawless nation. They were very fond of multiplying statistics of lawlessness, and of telling each other if they broke a simple rule, and they were very fond of compiling statistics and publishing them. No matter what subject one was dealing with in regard to Germany, the result of those characteristics would be found; and he was certain that the figures given in the paper with regard to food had been produced by those characteristics.

MR. CHARLES HECHT said he had read in the papers that instructions were given in Hamburg, and other dockyard towns, with a view to enabling the population to use their food more economically, and he would like to know whether the author had any special information on that point.

MR. SHUTTLEWOOD, in replying to the discussion, said that the Chairman had mentioned the question of food substitutes, and in that connection he might mention an article written by Captain Ozanne with regard to the bread substitute used in Germany at the present time. The report stated that the bread substitute when cut emitted a peculiar smell which at first was almost fruity and not exactly disagreeable, but afterwards grew sharper, and finally became overpowering and offensive; and that the crumb of such bread was at first more or less yellow to yellow-brown in colour and then became sticky, and when cut or broken hung together in long, sticky, tough threads. That was some indication of the nature of the food substitutes that were used. With regard to the efficiency of the blockade, he could only say that the present situation in Germany had been brought about by the blockade, which had been gradually contributing to the present result ever since it was introduced. It was at the present moment undoubtedly effective. With regard to statistics, it was very difficult to give any that were really reliable. The official statistics issued by the German Government were not accepted by the German Food Controller; and in connection with the potato crops, the statistics which were sent to the German Food Controller were ignored by him, and he ordered a fresh revision, because he regarded the statistics of the German Government as entirely misleading. Any statistics he personally could give would be equally so, because they would be drawn from the same source. With regard to obtaining nitrogen from the atmosphere, as the Chairman had said, the idea was not of German origin, and he thought it had first been developed in this country. The

* In 1898 Sir William Crookes, in his Presidential Address to the British Association at Bristol, spoke of the utilisation of atmospheric nitrogen for the manufacture of fertilisers, as a possible method of replacing the exhausted supplies of natural nitrates. The practical solution of the problem may be attributed to the Norwegian, Professor Birkeland, who, with the assistance of the engineer, Herr Eyde (also a Norwegian), established a factory for the production of nitrates near Christiania in 1903. A full account of the process and of the factory afterwards set up at Notodden will be found in a paper read before the Society in 1909 by Herr Eyde.—H. T. W.

Germans, however, had developed it and applied it in many directions; but he was not a scientist, and could not speak with any authority on the subject.

The Chairman, in proposing a hearty vote of thanks to the author for his interesting paper, said it appeared from what the author had said that the Germans had been more successful in the synthetic production of dyes than in the synthetic production of food.

The resolution was carried unanimously, and the meeting terminated.

INDIAN SECTION.

A meeting of the Indian Section was held on Thursday, March 14th, 1918, the Right Hon. J. Austen Chamberlain, M.P., in the chair. The paper read was "English Commerce with India, 1608–1658," by William Foster, C.I.E., Registrar and Superintendent of Records, India Office.

The text of the paper was printed in last week's *Journal*. The following is the discussion on the paper:—

DISCUSSION.

The Chairman (The Right Hon. J. Austen Chamberlain, M.P.) said that in tracing the origins of British trade with India the author had necessarily traced also the origins of the British connection with the Empire of India as it was known to-day, and it was very interesting to see the small beginnings from which so great a trade and so powerful an Empire had arisen. Trade had its romances no less than other aspects of our life that at first sight seemed more poetical, and if it was true to say that trade followed the flag, it was certainly also true to say that not infrequently the flag followed trade. The energetic, enterprising trader, responding to some personal desire for adventure or to some need for certain articles by his contemporaries, became, all unknowing, the discoverer and developer of new lands and the founder of new realms and empires. It was a far cry from the present time to the early days of the East India Company, but he thought that his late colleagues on the India Council who were present at the meeting must have felt—as he did—while listening to the paper, that after all the world sometimes came back on its old courses, and that events of long ago had a close analogy to the events of the present day. It was not merely that one found the indigo trade in the very early days with its difficulties, its partial failures, its gradual deterioration, just as had been seen again in more recent times when it fell from the great importance it once had, being superseded by chemical dyes, and dragging on a rather precarious existence, to assume, he hoped, in the future a fresh lease of good fortune and importance as science and skill were brought to bear more directly on its cultivation and preparation and the process of marketing it. It was not merely that one found old trades persisting, as, for example, cotton and indigo, but who would have expected to find a distressed Admiralty pressing the East India Company to supply saltpetre, just as the War Office or the Ministry of Munitions to-day asked the Secretary of State for India to do something in this or that direction for producing munitions of war? Then, again, there were complaints in the early days that the East India Company exported bullion. He had heard complaints of very much the same kind directed against the Secretary of State in Council in more recent times, and no doubt Mr. Currie would say that such complaints were heard in the City even to-day! So among many changes and vicissitudes the development of British trade with India had continued until at the present time it was one of the most important trades that this country possessed. He did not doubt that in one respect the war had been of advantage to India, because the Indian Government and Indian people had been stimulated to develop and make use of their own resources. They had been forced to look round and see how far they could provide for themselves articles or substitutes for articles which they had hitherto been content to buy from other countries. The inquiries undertaken in India for that purpose, and those conducted by Mr. Chadwick as to the markets available in European countries for Indian goods, promised to furnish great opportunities of development, of which he trusted India would take full advantage. Whatever might be the difficulties of adjusting British trade interests to those of India in any particular matter at any particular moment, in the long run those interests proved to be identical. There was plenty of room for both countries in friendly rivalry with each other or in assisting each other, and the prosperity of one could not be otherwise than advantageous to the other. He welcomed the prospects of a further development of trade between the two countries, and had listened with interest to the author's description of the first beginnings of that important trade.

Mr. Richard Burn, C.S.I., said that in Indian universities the study of Indian history and of Indian economics was now assuming a far greater importance than it had held in the past. Authorities in this country, from Lord Macaulay downwards, had frequently shown a good deal of contempt for Indian history, and even a more recent writer, Lord Morley, in his "Reflections," made rather depreciatory remarks about the subject, whilst Professor Rapson, a few years ago, almost apologised for producing a paper on Indian history. It must be admitted that Indian history as written hitherto had been largely a chronicle of kings and battles and petty squabbles, and it

was the need for revising such a chronicle, and showing more clearly the condition of the people and their economic state that made him welcome such a paper as the present one. During the last ten or fifteen years the study of economics from the Indian point of view had developed very considerably. In Bombay a School of Economics had been founded, and various university professors in other parts of India were opening *seminars* at which Indian students were being trained in research work. The author had stated that iron was exported to India, but had no chance there in competition with the cheaper products of India. To any one who knew India up to the last few years that statement was rather amusing, but since the foundation of the great factory by the Tata Brothers at Sakchi a return to those conditions might be possible, and he understood that the Indian Government had already commenced the manufacture of iron ships. Reference was made in the paper to the export of swords from India as being a trade of some importance. At the present time there were in India at least two very large collections of those weapons—at Jodhpur, and at Bikanir—which had never yet been examined by experts, but the Maharaja of Bikanir hoped to have them examined and classified, and to have an account published of the results. As a student of numismatics he had been much interested by the author's account of the method of remittances in cash to India from this country. The Spanish word *real* had been mentioned, and it was a curious fact that along the shores of the Persian Gulf the word "real" was still in common use as a generic term for foreign silver. The author stated that the most popular form of gold remittance was the English 20*s*. piece; in Hindustani at the present day the word for a sovereign was "guinea," which suggested that the guinea as well as the 20*s*. piece was exported.

MR. D. T. CHADWICK, I.C.S., said he hoped the author would continue his interesting examinations of the old records, and, in addition to noting the quantity and nature of the goods which came from India, would see if any light could be shed on the quality of those goods. One so frequently heard of deterioration, that any information on the grade of goods in olden days was of direct interest to all those in any way connected with economic or trade development in India. It was stated in the paper that Madras indigo in the early days was worse than other kinds, and it was well known that at the present time, three hundred years later, it still was so. He would like to know whether that was then a different kind from the indigo of Surat. It would also be interesting to know the different qualities of the large number of calico pieces that had been mentioned by the author as coming from India. It was often supposed that they were made from exceedingly fine types of cotton, but it was inconceivable to any one who had been engaged in agriculture in India that the whole of the Indian cotton crop in the old days was fine; there must always have been a much shorter staple cotton. One was led to wonder whether the old records would not also throw some light on the methods of industry formerly pursued in India, and how many of the articles were actually made and manufactured there. It was often said that in the old days India produced articles not only of exceedingly fine quality, but also of very great diversity, but the author's remarks on the subject of carpets seemed to convey the idea that it was a matter of very great difficulty in former times to induce the local workmen to alter their shapes and sizes, as it is to-day. An instance of trade persisting was the return trade of coral, which still went from Italy to India now, not through London, but by the aid of the banks, direct from the Italian merchants to the Indian dealers.

THE REV. FRANK PENNY (Madras Chaplain, retd.) said that for the past three hundred years there had been a great amount of misrepresentations as to the character of the men who worked in India for the East India Company in the early days. Those men, however, were the pick of the apprentices of the City of London, who had been educated at such schools as St. Paul's and Christ's Hospital, whose lists in the seventeenth century contained the names of many boys who afterwards distinguished themselves in India. There was a great deal of jealousy in this country on account of their success and the privileges, such as monopolies, that they enjoyed, and that jealousy gave rise to the false statements that had so often been made as to their moral character.

MR. G. P. BAKER said it must be observed that in connection with Mr. Foster's monumental work, on which he had been engaged for some years, the calicoes referred to in the period under review consisted of so-called printed and plain cottons. It might not be generally known that calico in the seventeenth and eighteenth centuries was never made in Europe at all but came entirely from India. The invention of calico printing was also due to India. In the early days, when the cotton goods came to England through the East India Company, they were sold either by public auction or by private sale, and then they were taken to the whitesters in the neighbourhood of London, who had their bleaching fields on the banks of the Wandle, the Lee and other rivers, and who had been taught how to bleach by the Dutch. Then would follow the dyeing of the Indian cloth and then the printing. The information about calico printing was not brought to this country by the servants of the East India Company but by the Jesuit Fathers. The balance of the trade was in favour of India until the era of invention when Arkwright invented the spinning-jenny and Watt the steam engine, and then the balance was turned in favour of England as against the East. Some of the most interesting documents in the library at the India

Office were the old warehouse sale books and catalogues of the East India Company. It appeared that the Governors of the Company held sales periodically, once in six months, the articles sold including saltpetre, coffee, china, porcelain, tea, shellac, and a very little cotton. The sales were extensively advertised and attracted many buyers from the Continent. The sale books showed that in 1660 the tea realised from 15*s.* to 18*s.* 3*d.* per lb., shellac £27 per cwt., and rhubarb 10*s.* 6*d.* per lb. The Carmania wool mentioned he supposed was Khorassan wool; it was a very fine quality wool and made the cardinal hats so popular in Europe at that period. In 1704 a six days' sale by the East India Company realised £255,000. With regard to calico prints—the section of the trade which he had been investigating—he found an entry showing that in one day 22,000 pieces of chintz were sold at from 8*s.* 3*d.* to 10*s.* 9*d.* per piece. It was interesting to note that many words well known in the Manchester trade to-day were derived from Indian words: for instance, chintz, dungaree, ginghams, dimities, and so forth. Mr. Foster, as a true editor of the records, had not indulged in the romance of trade to which the Chairman alluded. The doings of our merchant adventurers offered many stories, which he hoped might yet form part of Mr. Foster's work.

Lieut.-Colonel Sir David Prain, C.M.G., C.I.E., F.R.S. (Director of the Royal Botanic Gardens, Kew), said that Mr. Chadwick had asked the author, with reference to the quality of the indigo produced on the Coromandel Coast as compared with the indigo of Surat, whether the two were the product of the same plant. That was a question which it seemed only fair to the author that a botanist present should answer on his behalf, and it was one that had already been examined and the evidence had been recorded. The references and specimens available indicated that Madras indigo was the product of the plant described in nearly all text-books dealing with indigo as *Indigofera tinctoria.* He believed, however, that *Indigofera tinctoria* never was used as a source of indigo to any appreciable extent except in Madras. Certainly the plant which yielded the indigo exported from Surat was quite a different one. That plant was still grown as a source of indigo in the Italian colony of Eritrea, and was still sparingly cultivated by the Indian natives themselves in Sind, Rajputana and the Kistna uplands. The author had mentioned that the Dutch on the Malabar Coast were the rivals of our people at Surat in the export of indigo to Europe. It was known from a Dutch author that another plant, different from the source of Surat indigo and from that of Madras indigo, was then cultivated in Malabar. It was that third plant, which was not of Indian but of Malayan origin, that, after the cultivation of indigo was taken up again by the East India Company towards the end of the eighteenth century, was grown in Bengal, Bihar and Orissa.

Mr. William Coldstream proposed a vote of thanks to the author for his paper, the motion being seconded by Mr. Laurence Currie, and carried unanimously.

Mr. Foster, in reply, said that, with reference to Mr. Baker's remark about Carmania wool, he thought that wool had nothing to do with Khorassan, but with Kerman in Persia, whose carpets and shawls were still valued. Sir Percy Sykes had done a great deal to revive the demand for them. He was very glad to hear the remarks Sir David Prain had made with regard to indigo, the information given being quite new to him.

On behalf of the Indian Section Committee, Sir Charles S. Bayley, G.C.I.E., K.C.I.E., thanked Mr. Chamberlain for presiding.

The Chairman, in concluding the meeting, said a correspondent had reminded him by letter that morning that the present year was the centenary of the death of Warren Hastings, and had suggested that the house in which he used to live near the Marble Arch should be marked by a tablet. He (Mr. Chamberlain) was under the impression that it was so marked, but if it was not, he thought the Indian Section might perhaps jog the memory of the London County Council, who frequently commemorated the association of great men with London localities. He only regretted that, on the other side of the India Office to that on which the fine statue of Clive stood, there was not a statue to the other great pioneer and founder of Indian government, Warren Hastings.

The correspondent alluded to by Mr. Chamberlain in his closing remarks, Mr. Wilmot Corfield (Calcutta Historical Society), writes pointing out that the house in Park Lane where Warren Hastings lived has been demolished and a new one erected. He suggests that a tablet should be placed, not upon the present building, but upon or near the park railings opposite, deferring the larger question of a statue to a more convenient season.

"FABRICATED" SHIPS.

One of the most interesting but least known developments of the present shipbuilding effort in which Great Britain has led the way is that of "fabricated" ships. It is described in the *Times* of April 18th. A "fabricated" ship is a vessel the component parts of which are manufactured in other than shipbuilding yards. These component parts are transported to shipbuilding yards, assembled there, and put together as complete ships.

When the State undertook the reorganisation of the United Kingdom's mercantile shipbuilding industry, the principle of standardisation was

naturally adopted because in mass production of a specific object the highest possible speed of output is obtainable. A series of standard ships were designed, and contracts to build them were given out to the private yards of the country. As supplies of steel and labour increased and promised a margin over and above the requirements of the existing controlled shipyards, the idea was carried a stage further. The fabrication of ships was decided on and the necessary provision made. The aim of the Admiralty Deputy-Controller's Department was still further to increase speed of production. As matters stood, all the shipbuilding yards, engine factories, and boiler shops were largely occupied with standard ship work. There were, however, many other industrial establishments in the country doing work closely resembling shipbuilding and marine engineering. Among them were bridge-building yards and land engine factories. The majority of them were in inland centres and remote from launching water; but, taken altogether, their resources were so great that it was felt that they ought to be used.

"Fabrication" solved the problem, and a ship was designed the material of which could be satisfactorily fabricated in the bridge yards. It is a bigger vessel than most of the standard ships, and there is not a curved frame in it. Size and weight of unit of construction are limited, so that transport is easy, and powerful gear for placing it in position is unnecessary. To avoid the same difficulties as regards machinery supply, geared turbines have been adopted instead of reciprocating engines. Every part of the complete ship can, in fact, be fabricated in inland establishments selected near the steel-mills which have never done ship or marine engine work, and can be transported by ordinary means to the seaboard. With all the slips in private yards filled, it was necessary to look elsewhere for sites for assembling yards. The national shipyards on the Bristol Channel were laid out for the purpose, and private undertakings of the same character exist or are projected with the concurrence of the Admiralty elsewhere. The objection has been urged that State-owned establishments ought not to have been set up until it was definitely known that the contract industry could not provide the required additional facilities. But it should not be overlooked that in carrying out its plans the State has a call on labour which is not available to contractors. The bulk of it is unskilled. Labour is, however, being trained in the use of pneumatic riveters and caulking tools, and will be (already it is in a large number of instances) sufficiently expert to put the assembled fabricated ships together.

The fabrication of the material of ships and engines has now been organised over a considerable area, local committees being responsible in certain districts for definite deliveries of a ship, or a number of ships, in specified periods. Moreover, fabricated ships are taking shape in several assembling yards. Before long, vessels of the type should represent a very considerable addition to the tonnage output. In the strictest possible sense of the term they will be additional, for their production will have involved absolutely no interference either with the contract industry or its supplies of labour and material. The State's fabricated ship enterprise increases the tonnage output by tapping new sources which are inaccessible or impossible to the private shipbuilder.

GENERAL NOTES.

Overseas Trade.—The following have been appointed to serve as a Committee to advise the Department of Overseas Trade (Development and Intelligence) on matters relating to the activities of the department: Sir Francis Barker, representing the Federation of British Industries; Sir Algernon F. Firth, Bt., representing the Association of Chambers of Commerce of the United Kingdom; Mr. W. H. N. Goschen; Mr. W. L. Hichens; The Right Hon. Lord Inchcape, G.C.M.G.; Mr. Walter Leaf; Mr. Kenneth Lee; Mr. G. A. Moore; Mr. J. W. Murray; Sir George A. Riddell, Bt.; Mr. C. V. Sale; Captain Albert Smith, M.P.; Colonel Frank H. Wedgwood.

Wolfram in Kedah, F.M.S.—A correspondent of the *Mining Journal* writes that the sanguine expectations entertained of the wolfram discovery at Sungei Sintok, near Changloon, Kedah, are being substantiated by further examinations. The ore is found in quartz, and, of course, systematic prospecting, which is to be taken in hand shortly, will be necessary before definite opinion can be formed. However, there can be no doubt the mine is rich, and the owners expect to get an output of at least fifty tons of concentrates per month. The ore is very coarse, and lumps weighing as much as fifty kattis are not uncommon. It is believed to be the richest find made in the East. A curious feature is that no extension of the deposit outside the original area has so far been revealed.

South African Timber.—It is not so very long ago that South African timber was, taken all round, considered of little value. Now that imported timber has gone up in the market, according to *South Africa*, many virtues have been discovered in the native timber which previously were unknown. In consequence, South African timber has come to the front, so that it figures prominently in many issues. Sawing timber, such as Cape pine, poplar, yellow-wood, blue gum, and other varieties, cut into standard deals of 3 in. by 9 in., is quoted at $10\frac{1}{2}d.$ to $1s.$ per foot. This timber is mostly used for boxes and packing-cases, as well as substitutes in the mines and buildings for the imported Baltic and Oregon woods. Mining poles and sawing timber are quoted at fair average values.

MEETINGS OF THE SOCIETY.

Ordinary Meetings.

Wednesday afternoons, at 4.30 p.m.:—

May 1.—George Martineau, C.B., "Sugar from several Points of View." The Right Hon. Lord Balfour of Burleigh, K.T., G.C.M.G., G.C.V.O., will preside.

May 8.—John B. Farmer, D.Sc., M.A., F.L.S., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry."

May 15.—Percy Groom, M.A., D.Sc., F.L.S., Professor of Technology of Woods and Fibres, Imperial College of Science and Technology, "The Timber Industry." Sir John Stirling-Maxwell, Bt., will preside.

May 29.—Martin O. Forster, D.Sc., Ph.D., F.R.S., "Organic Chemistry in Relation to Industry." Sir William A. Tilden, D.Sc., LL.D., F.R.S., will preside.

Indian Section.

Hon. Sir Dinshaw E. Wacha, Chairman, Bombay Millowners' Association, "The Cotton-mill Industry of India."

[The date will be announced later.]

Colonial Section.

Tuesday afternoon, at 4.30 p.m.:—

April 30.—Sir Walter Egerton, K.C.M.G., LL.D., Governor of British Guiana, 1912–17, "British Guiana." Sir Everard im Thurn, K.C.M.G., C.B., will preside.

Special Lectures.

A special course of three lectures on "The Freedom of the Sea" will be delivered on Thursdays, May 2nd, 9th, and 16th, at 4.30 p.m.

Lecture I.—By Gerard Fiennes. Chairman, J. L. Garvin.

Syllabus.

The Freedom of the Seas.

Freedom without Law.—The first maritime peoples—The Viking Age—Edward III. and the sovereignty of the seas—The Hansa—The Italian Republics in the Mediterranean.

Law without Freedom.—The discovery of the passage round the Cape of Good Hope and of America—The Bull of Alexander VI.—Henry VII.'s licence to the Cabots—Elizabeth's views—The English and Dutch—The war of Jenkins's Ear—The mercantile system—Berlin decrees—Orders in Council.

Law and Freedom.—Britain's work—Freedom "made in Germany."

Lecture II.—By Sir Francis Taylor Piggott, M.A., LL.M., Chief Justice of Hong-Kong, 1905–12. Chairman, Lord Sanderson, G.C.B., K.C.M.G.

Syllabus.

The Freedom of the Sea in War.

The breakdown of International Law due to unpractical theories—Effect of war on the Freedom of the Seas—Limitations of neutral commerce with the enemy—Rule of 1756—All interference with neutrals based on prevention of assistance to the enemy—"Free ships, free goods": the neutral doctrine essential to maintain the enemy's fleet—Foundation of a spurious Freedom of the Sea claimed by enemies and neutrals: consistent opposition to the doctrine by England—The armed neutralities—American War of Independence—Bonaparte's theories—Immunity of private property at sea—Declaration of Paris—Maintenance of English principles of belligerency essential to an effective League of Nations.

Lecture III.—By John Leyland. Chairman, Admiral Sir Edmond John Warre Slade, K.C.I.E., K.C.V.O., R.N.

Syllabus.

The German "Freedom of the Sea."

Britain the great upholder of the Freedom of the Seas—The meaning of the term—How it was regarded by Grotius—How we came to be denounced as the "tyrants of the sea"—The attitude and policy of Napoleon—His claim to be the liberator from tyranny—The modern German claim a protest against British sea-power—An analysis of the claim—Its real meaning—The view held and expressed in the United States—The agreements and understandings with Prussia—President Wilson's declaration—How it is in conflict with the German claim—The need of a right understanding of the subject.

Cobb Lectures.

"Recent Developments in Leather Chemistry," by Henry R. Procter, D.Sc., F.I.C., Emeritus Professor of the Chemistry of Leather Manufacture, Leeds University, Director of the Procter International Research Laboratory. Two Lectures.

Syllabus.

Lecture I.—May 13.—Structure and chemistry of skin—Processes for removal of hair and epidermis—Removal of lime and preparation for tanning—Use of bacteria and enzymes—Dehydration and separation of fibrils—The pickling process—Nature of colloid swelling.

Lecture II.—May 14.—The conversion of the pelt into leather, and the nature of the change—tannage with mineral salts—Alumina tannage—Chrome tannage—Vegetable and synthetic tannins—Tannages with aldehydes, quinones and bromine, and with colloidal precipitates—Oil tannage—Summary.

London: Printed by William Clowes & Sons, Ltd., Duke Street, Stamford Street, S.E., and published for the Royal Society of Arts by G. Bell & Sons, Ltd., York House, Portugal Street, W.C., in the Parish of St. Clement Danes, in the City of Westminster.—April 26, 1918.

No. 3415. MAY 3, 1918. Vol. LXVI.

JOURNAL
OF THE
ROYAL SOCIETY OF ARTS

CONTENTS.

Published every Friday. *Price to Non-Fellows, 6d.*

LONDON:
Published for the Society by G. BELL & SONS, Ltd., York House, Portugal St., W.C.

REGISTERED AS A NEWSPAPER.

NOTICES.

NEXT WEEK.

WEDNESDAY, MAY 8th, at 4.30 p.m. (Ordinary Meeting.) JOHN B. FARMER, M.A., D.Sc., F.R.S., Professor of Botany, Imperial College of Science and Technology, "The Rubber Planting Industry." SIR EDWARD ROSLING, Chairman of the Rubber-Growers' Association, will preside.

THURSDAY, MAY 9th, at 4.30 p.m. (Special Lecture.) SIR FRANCIS PIGGOTT, M.A., LL.M., Chief Justice of Hong-Kong, 1905–12, "The Freedom of the Sea in War." LORD SANDERSON, G.C.B., K.C.M.G., will preside.

Further particulars of the Society's meetings were published in the last issue of the *Journal.*

COLONIAL SECTION.

Tuesday afternoon, April 30th; SIR EVERARD IM THURN, K.C.M.G., C.B., in the chair. A paper on "British Guiana" was read by SIR WALTER EGERTON, K.C.M.G., LL.D., Governor of British Guiana, 1912–17.

The paper and discussion will be published in a subsequent number of the *Journal.*

NINETEENTH ORDINARY MEETING.

Wednesday afternoon, May 1st; The RIGHT HON. LORD BALFOUR OF BURLEIGH, K.T., G.C.M.G., G.C.V.O., in the chair. A paper by Mr. GEORGE MARTINEAU, C.B., on "Sugar from Several Points of View" was read by Mr. EDWARD R. DAVSON, President of the Associated West Indian Chambers of Commerce.

The paper and discussion will be published in a subsequent number of the *Journal.*

SPECIAL LECTURE ON "THE FREEDOM OF THE SEAS."

Thursday afternoon, May 2nd; Mr. J. L. GARVIN in the chair. A special lecture on "The Freedom of the Seas" was delivered by Mr. GERARD FIENNES.

The lecture will be published in a subsequent number of the *Journal.*

Journal of the Royal Society of Arts.

No. 3,415. VOL. LXVI.

FRIDAY, MAY 3, 1918.

All communications for the Society should be addressed to the Secretary, John Street, Adelphi, W.C. (2)

PROCEEDINGS OF THE SOCIETY.

SIXTEENTH ORDINARY MEETING.

Wednesday, April 10th, 1918; PROFESSOR WILLIAM BATESON, D.Sc., F.R.S., Director of the John Innes Horticultural Institution, in the chair.

The following candidates were proposed for election as Fellows of the Society:—

Barrett, Frank, Grimsby.
Campbell, Oliver Hering, London.
Chopra, Igbal Chand, India.
Cobbett, Colonel George Talbot Burrows, London.
Cockill, Harry, Southport.
Davies, Frederick Herbert, London.
Dobson, D. Bennett, Thames Ditton.
Feltoe, Rev. Charles Lett, D.D., Dover.
FitzGerald, Francis William, London.
Forbes-Bentley, Lieutenant Rupert, Beckley.
Harrison, Joseph, Hon.A.R.C.A.(Lond.), Nottingham.
Hugh, James, Bothwell, Scotland.
Ishii, Shinji, London.
Lathe, Alfred, Bilston.
Nisbett, G. H., M.I.E.E., Liverpool.
Reddan, William Holmes, Mansfield.
Singer, Edgar Ratcliffe, Frome.
Statham, Noel, New York City, U.S.A.
Taylor, Arthur Walford, London.
Tuck, G. O., Kentucky, U.S.A.
Underwood, Oliver, London.
Watson, Charles Edward, Wall, North Tyne.

The following candidates were balloted for and duly elected Fellows of the Society:—

Aiyar, K. V. Venkataramana, Madras, India.
Besant, A. Digby, London.
Boyd, John T. M., New Zealand.
Butson, Cecil W., Hankow, China.
Hosain, Dr. S. A., Mambuw, Federated Malay States.
Jackson, Right Hon. Frederick Huth, M.A., London.
Meling, Einar, Norway.
Muntz, Sir Gerard Albert, Bt., Stratford-on-Avon.
Narasimham, G., Madras, India.
Preston, Arthur Phillips, Teddington.
Rae, William, M.Inst.M., Kinlochleven, Argyllshire.
Simkins, Alfred George, London.
Spencer, Samuel, Assoc.Inst.C.E., London.
Stephens, Albert John, Gloucester.
Webb, Herbert Charles, London.
Wilson, Edmund Richardson, L.R.I.B.A., New Zealand.

THE CHAIRMAN, in opening the meeting, said that he had known Dr. Balls for many years as a vigorous and active worker both in the domain of pure science and in that of the application of science to the production of cotton. Science had scarcely yet been applied at all to the tropical and sub-tropical branches of agriculture. A good deal had been done in our own country in regard to agriculture, but very little in regard to tropical agriculture. For instance, anyone who knew something of genetic science and its possibilities, in walking over rubber plantations in the Malay Peninsula would feel amazed at the practices which still prevailed amongst planters there, and he was quite sure that the application of a trained intelligence for a few years would work a revolution. The good, bad, and indifferent plants were being cultivated. One rubber tree would produce two hundred units of rubber, and another only one, but all sorts were grown together in a batch, occupying equal space and attention. In a reasonable time it would be possible to produce a pure strain of best trees only. The same thing also applied to coco-nuts. Mr. Balls had experience of the sub-tropical plant, cotton, and he had added much to our knowledge of that subject.

The paper read was—

SOME APPLICATIONS OF RESEARCH TO THE COTTON INDUSTRY.*

By W. LAWRENCE BALLS, Sc.D.,
Late Fellow of St. John's College, Cambridge; Fine Cotton Spinners' Association; formerly of the Khedivial Agricultural Society of Egypt, etc.

Most of the research data to be utilised in this paper relate only indirectly to that section of the cotton trade which is most familiar to us at home; but it should be obvious that any knowledge of the nature of the raw material must necessarily react upon its control and utilisation.

* In the course of the paper, as delivered, lantern-slides were employed to illustrate the statistical data quoted. For the convenience of readers of the present text who may desire to study the matter more closely, a reference to these is made (where such are drawn from data already published) by giving the abbreviated title of the publication and the figure number within such publication. The publications used and their abbreviations are as follows:—

"The Cotton Plant in Egypt." Macmillan: London, 1912. (C.P.E.)
"The Development and Properties of Raw Cotton." A. and C. Black: London, 1914. (R.C.)
"Analyses of Agricultural Yield." Parts I. to III. *Phil. Trans. Roy. Soc.*, 1915–6. (A.A.Y. I., II., III.)
Reference to other papers by the author are given by a single number in parentheses, this number referring to the full list of such papers given in the first two books above mentioned.

Introduction.

The whole technique of the cotton manufacture—our largest export industry—is based upon the properties of single unicellular seed-hairs. Until we know the properties of those hairs, which in its turn requires a knowledge of the manner in which they are formed, and particularly until we know those properties in relation to their behaviour in the process of spinning, we cannot attempt to construct a common scientific language by means of which the Grower and the User of cotton may exchange ideas and information, and so may work together in order to produce the best practicable results from their raw material. This raw material is not so much the cotton hair itself, but is rather the sex-cell of the cotton plant, and the embryo relating therefrom.

Most of the audience will probably admit that our perspective of the cotton trade is exaggerated. We see the magnitude of our Lancashire cotton industry, we are properly impressed by the ingenuity and organisation which it involves, and we scarcely perceive a glimpse of that which lies behind it in the shape of agriculture. In the previous paragraph we have tried to correct this perspective, so as to obtain a general view of the cotton trade as a whole.

The study of the cotton crop is naturally subdivided into two halves of identical importance. Those halves are—the plant itself, and the environment in which it lives.

Any particular plant has certain constitutional capabilities, which may be peculiar to itself, or similar to those of its neighbours. These capabilities have been transmitted to it by the action of what we call heredity, and are fixed for it definitely at the moment of fertilisation. Such constitutional idiosyncrasies, however, resemble those of a photographic plate—which may be fast or slow, red-sensitive or blue-sensitive, and so forth—in that they are potentialities only; these potentialities have to be *developed* by the interaction which takes place between the organism and its environment in the process of growth and existence, just as the potentialities of the plate are developed in different ways by the action of different intensities and colours of light.

It is really somewhat remarkable that this very definite distinction has been so frequently missed. Many well-intentioned agriculturists have endeavoured to make "silk purses from sows' ears" by growing unsuitable seed in suitable places. Others have cast the pearls of good seed before swine by planting in unsuitable localities.

The examples with which we propose to deal to-day are all inter-connected, and relate to all parts of the cotton trade. They are as follows:—

In the first place, the preparation, propagation, and cultivation of pure strains or pure lines of cotton plants. Arising out of the study of these plants, we can examine what is meant by the length of the lint; the full investigation of this has only become possible quite recently, by means of a new piece of scientific apparatus. Thirdly, we shall sketch a history of the study of root asphyxiation in relation to the Egyptian cotton crop, an issue involving many millions of pounds; and in the course of so doing we shall see in the fourth place how this study compelled the natural development of new methods for examining and recording the state of the cotton crop, and thus incidentally provided practical means for making precision crop reports and forecasts.

The Cultivation of Pure Cotton.

The greater precision brought into the study of heredity by the re-discovery of Mendel's Law led to a class of work which was first exploited by Professor Johannsen of Copenhagen, known as pure line studies, or pure strain studies. Johannsen worked with beans and showed that from cultures of bean plants, which were considered uniform from a horticultural standpoint, it was possible to isolate many separate kinds which differed, for instance, with regard to the average size of the seed they produced.

When the author began his researches into the course of heredity in cotton in 1905, we had very little previous knowledge to guide us. A general conviction existed that the yield of the Egyptian cotton crop was deteriorating, and there was an impression (which we now know to be erroneous) that this deterioration would be dealt with primarily by appropriate breeding of new kinds of cotton. Certainly, although there was a general impression that uniform cotton was better than irregular cotton, we did not anticipate the possibilities which lay behind a mere repetition of Johannsen's studies, using the cotton plant instead of the bean plant.

It will assist understanding if we sketch briefly the early history of this work. We began by taking natural seed from single plants of the 1904 crop, and raising small families from these in 1905. Using methods suggested by analogy with previous experimental work (conducted as an assistant to our Chairman of to-day, and to Professor Biffen), the detailed

examination of these families showed in the course of 1905 that the commercially-grown seed with which we had started was very far indeed from being the seed of "pure lines" in Johannsen's sense (5, 8).

In the first place, even though we were not able to examine more than a limited number of the characteristics of the plants, and although the families we raised were quite small, it was most unusual to find a family in which all the plants resembled one another. It should be added that by the word "resemblance," we mean constitutional resemblance; the distinction between peculiarities of a plant due to its constitution as against peculiarities due to accidents of the environment, was decided partly by *à priori* reasoning in the first instance, and determined accurately by experiment in subsequent years.

Now, the fact that a group of plants derived from a common parent was not constitutionally uniform, indicated that the parent plant must have been a hybrid, and this great abundance of hybrids thus detected in those plants of 1904 which we had taken at random to begin with, indicated that an appreciable amount of intercrossing must be taking place between flower and flower under the conditions of the ordinary Egyptian field crop of cotton. Further, even with this rough material from which we started, we were able to show in 1905 that certain plants on our plot had undoubtedly originated through cross-pollination in the previous year and not earlier.

This work was extended to provide a numerical determination of the chance of crossing as compared with the chance of self-fertilisation, which chance was found to be approximately one in ten (C.P.E. Chap. 7). This amount of crossing is amply sufficient to contaminate hopelessly any pure line pedigree within only two or three years; thus a serious experimental difficulty with which we had thenceforward to contend was the prevention of crossing on the breeding-plot. It should be added that this conclusion concerning the chance of contamination by crossing in the cotton crop ran counter to almost all accepted notions on the subject; but was confirmed quite independently in the following year by Mr. H. Martin Leake, in India, and by many others since, while our own researches showed later that certain circumstances could produce much higher rates, rising even to ostensibly complete prevention of self-fertilisation.

In this early stage of the researches it seemed (as indeed it was) much more useful to attempt to trace the working of Mendel's Law by study of these natural hybrids, or, better still, by the deliberate making of hybrids for experimental purposes, than merely to isolate pure lines. Acting in the spirit engendered by association as a student with our Chairman, in tackling the difficult subject where apparent anomalies abounded, rather than the easy one, our further experimental work was directed primarily to the study of crosses between American upland cottons and Egyptian—practically an inter-species cross—rather than to inter-Egyptian crosses (15, 20, 33).

The attempt was an ambitious one, and was only made possible by the enlightened attitude of the Khedivial Agricultural Society, and its then president, the late Sultan of Egypt; it was, in fact, much more than a one-man proposition, or even a two-man proposition. At the same time it was well worth the trouble, for in many cases we traced definite simple rules of inheritance on Mendelian lines through most complex phenomena (C.P.E. Figs. 53, 69, 70), and in even more cases we found most complex inheritance in pedigrees which, on the face of them, appeared to have been quite simple (19).

The characteristics of commercial value are nearly all measurable characteristics, such as length and breadth and thickness, and are rarely "attributes" such as colour. As our work extended to the study of the inheritance of these measurable features, we were continually faced with the difficulty that we did not know enough about the effect of the environment upon the degree of manifestation to which such characteristics attained; we did not know to what extent or in what manner a cotton plant which had inherited long lint hairs might have those hairs shortened, or even made longer, by the action of the environment.

So many problems of this kind arose, and they were so often of obvious practical interest as well as being fundamentally important in relation to our researches on heredity, that the work of my assistant—Mr. Holton—and myself was diverted more and more, up to the end of 1912, to this aspect of the cotton plant, with results to which we shall return later in the course of this paper.

At the end of 1912 came an insistent official demand from the Agricultural Department, to which we had been transferred, for a new cotton to replace the deteriorated Brown Egyptian or Afifi (32). One thing at least was perfectly obvious, in the light of our seven years' experience, namely, that it was the easiest thing in the world to introduce a new cotton

Alternatively, one of the most difficult things in the world was to predict what the agricultural behaviour of plants in bulk would be, from the behaviour of a few parent plants grown on a breeding-plot. Lastly, it was self-evident to us, though apparently not to others, that to introduce a new variety of cotton in an impure state (however slight the percentage of impurity), or even allow it to become contaminated by natural crossing (much less by seed mixture), during its propagation from the breeding-plot to field cultivation, was simply to condemn one's work to the same failure which had sooner or later resulted with every other variety of cotton which had ever been developed in Egypt or anywhere else in the world. This meant, in practice, that a system of continual seed renewal was inevitable.

Thus, so far from being a matter which could be determined or settled by the work of one or two scientists, it was an administrative proposition, based on scientific research and involving a revolution in the system of seed supply for Egyptian cotton.

The prospects of this revolution were accepted at the time, and a system of pure-strain seed-supply was initiated, though it was never carried through to completion.

In developing this system, we had first to consider what cotton should be propagated as most nearly meeting the official demand. Obviously, the prime essential was that the strain should be a pure one; further, it was undesirable to introduce the use of any but Egyptian stocks. All strains bred from our deliberate hybrids of American or even Egyptian cottons were therefore ruled out, and we restricted our work to strains which had been obtained simply by choosing individual plants of commercial Egyptian varieties. These plants and their descendants had been self-fertilised for a number of generations ranging from seven to two, and all their various characteristics measured, registered and studied until such of them as had been hybrids originally had been split down to purity.

One strain known as No. 77, whose pedigree dated back to 1904 and had been published in some detail (5, 15, 33), which we had used as a parent in our crosses with American cottons, seemed to be moderately suitable for tentative trial (32), though the direction of our past work had not been towards a deliberate isolation of the best Egyptian cottons from the existing mixtures (7), but rather towards the study of heredity in cotton in the hope of ultimately making more radical improvements.

Another strain of brown cotton called No. 95, was propagated side by side with this (C.P.E. p. 109), and one from long cotton known as No. 310 was put forward out of curiosity, to see whether it was possible to grow lint in Egypt of the same order of quality as that of the Sea Islands. Simultaneously, the study of inter-Egyptian crosses and the isolation of more pure strains of Egyptian cotton was extended in the search for ideal plants, and No. 111 was found, purified and propagated to a ton of seed between September 1911 and November 1913; but most of our energies for the next two years were expended on devising and executing means (34) whereby these four pure strains could be propagated into sufficient quantity to sow fifty or a hundred acres of land without contamination from other cottons by natural crossing.

Without entering into details, we may note that most of the transference of pollen from flower to flower in Egypt is effected by bees; if bees can be kept away, foreign pollen is also kept away, and so for the first stage we sowed the protected seed from single pure-strain plants in cages built up of angle-iron and brass-wire gauze of 144 apertures to the square inch, each cage measuring 10 metres by 14 in area, and 2 metres in height, built partly on a system of sectional unit panels of gauze which we designed.

For the following year (1913) the seed from these cages, again spaced at wide intervals so as to obtain the largest possible production of seed per plant, covered areas of 20 acres or so, and obviously could no longer be protected by gauze, so we endeavoured to deceive the bees by surrounding such areas with a belt of plants some seven to ten rows deep; these were plants nominally of the same strain, for whose parents we had not been able to find room for protection in the cages in the previous year. The motive behind this arrangement was that any bee reaching the propagation plot after visiting ordinary cotton outside, should, so to speak, filter itself upon the plants of the Belt from some at least of the foreign pollen which it carried, before reaching the cage-bred and pure plants of the main plot. The seed from the plants growing in the Belt was destined, of course, to be destroyed.

Such was, in outline, the system we devised, and this was to have been combined with a system of seed distribution year by year, so as to provide for continual and perpetual renewal, of the seed of all Egypt year by year as a matter of pure routine from the handfuls of various suitable strains, maintained pure with all laboratory precautions, at the Central Seed Station at Giza; the inevitable deterioration of a variety of cotton exposed to contamination

in the field would thus be counteracted by continuous renewal year by year from the pure stock.

Seed mixture and natural crossing can be prevented by the usual research precautions in the laboratory; on the propagation plot they can be minimised by arrangements of belting and by zonal collection of seed, but it is hopeless to attempt to prevent such contamination at a later stage. It must inevitably take place, until we can discover or breed a cotton plant which is naturally self-fertilised. Further, the effect of such mixture augments itself enormously year by year, so that the presence of 2 per cent. of natural hybrids in a handful of pure-strain seed can convert 30 per cent. of the individuals in that strain into rogues at the end of only three years (32).

It may be noted incidentally that during the course of this work we raised more than a metric ton of apparently pure seed by the autumn of 1913, where a single seed had been planted in 1911, and this not once, but in the case of three separate plants. I believe that this is practically a record for artificial seed propagation, and I look back now with some amusement on the fact that, though it was achieved in the teeth of almost every conceivable misadventure, I was informed that it was much too slow.

With the departure of Mr. Holton, and then of the author, from Egypt at the end of 1913, this work was practically put in abeyance.

Trials were made of these four strains, and No. 111 turned out to be definitely superior to any other Egyptian cotton from the agricultural point of view, justifying our judgment in choosing it deliberately. No. 95 was remarkably and unexpectedly good in every spinning test. The strain first elected for propagation as being thoroughly well known (No. 77) turned out only moderately successful, as had been expected at first (32), while the very long cotton (No. 310), although its yield was no better than we had anticipated, showed that Egypt could grow cotton comparable to that of the Sea Islands, if she cares to take the trouble.

The most important result, however, of all this mainly wasted effort, was that these pure-strain cottons, when put through the spinning-mills, behaved far better than expert judgment and handling of the lint had anticipated. Perhaps the most remarkable case was that of a very ugly sample of No. 77, with regard to which the author received two letters from the spinner at intervals of a week; the first letter stated that the sample was very bad, but it would be included in the spinning tests solely because of the interest attaching to any performance of these pure strains. The second letter showed that this ugly duckling had headed the list of six samples in the test, giving the strongest yarn of any. We are ignorant as to what this peculiarity may mean; but it can scarcely be accidental that three strains, chosen at random from the Egyptian cotton-complex, without any knowledge whatever of their spinning possibilities, chosen merely because they happened to be the only well-known pure strains available, should falsify the expectations of expert judges of raw cotton in this manner.

The cultivation of these four strains has now been abandoned, but two further facts may be noted. Firstly, that No. 111, isolated in 1911 from Assili, was an excellent cropper, and was indifferent only in the spinning tests; yet it was as perfect in the uniformity of its lint-length as any cotton known; undoubtedly there is something lacking in our text-book precepts. Secondly, at least one strain which had been isolated since 1906, and had been still pure at eight years old when sown in the field in 1914, was badly contaminated by 1917; caging or seed-renewal had not been practised, but only especial care in handling the seed: our predictions as to the importance of natural crossing are thus completely fulfilled.

Length of Staple.

One of our most pressing needs at the present time is the provision of a language common to both the spinners and the growers of cotton, such that the grower can be informed exactly what kind of cotton the spinner requires (R.C. Chap. V.). This language can only be synthesised by scientific study of the properties of yarn in relation to the hairs of which it is composed.

Amongst the many physical properties of cotton hairs, one of the most obvious is the length. We may now proceed to indicate the difficulties involved in the study of this simplest of all the hair properties, from which may be gathered some idea of the nature of the elaborate technique which has yet to be constructed patiently, before this scientific analysis of a practical matter can be carried far enough to provide the common language which we need.

It will have been gathered from the previous section of this paper that the ordinary commercial crop of cotton is an impure culture, which, from the genetic standpoint, is so far from being a pure strain in Johannsen's sense that it approaches rather to an analogy with Humanity; for although each individual plant is not unique in constitution, yet there are innumerable differences existing within a single field. Amongst these differences are those relating to the length of the lint, over and above such modifications of lint-length as may be

caused by environment. Further, these genetic differences take two forms: firstly, there are differences in what we may call the Mean Maximum length of the lint produced on any one seed, and, secondly, there are differences in the degree of Variation in lint-length on different parts of the same seed. Consequently, in respect of the latter, a single plant (or equally, a pure-strain population of plants) may produce most irregular lint, the hairs from one end of each seed being very much shorter than those from the other end, while every graduation is found between these extremes. On the other hand, suitably chosen pure strains are capable of making lint not only more regular in staple than are our present cottons, but may conceivably produce a greater degree of natural regularity than machinery can enforce.

It probably needs no further explanation for the reader to see that any detailed study of the influence of environment upon the inherited lint-length capacity of the plant was obliged to wait until pure strains could be cultivated more or less in bulk; otherwise the environmental effects were likely to be masked under the constitutional mixture, this mixture being not only a mixture of lint-lengths, *qua* lint-lengths, but also a mixture of reaction-capacity for the operation of building up lint-lengths.

Our possession of this pure-strain material enabled us to conduct a series of determinations day by day, throughout two separate growing seasons, showing the effect of various conditions of soil and weather in modifying the length of the lint. These have been published in book form (R.C., especially Figs. 14 and 15), and we need not further mention them here except to say that these variations were all traced to comparatively simple causation.

In all these studies, however, until last year, we had not a full technique at our disposal, and since this is the point of immediate interest a short explanation of the way in which the length of staple is ascertained must now be given.

In the ordinary way, the length is determined by examination of the lint cotton, from which the seed has been removed in the process of ginning. The expert grader pulls a tuft of hairs from this lint in a particular manner, usually lays the tuft on his coat sleeve, and then assesses, with or without a measuring scale, the length of the tuft: in this case, the length measured is the length of the majority of the longer hairs; it is not the length of the few very long hairs, since these are not conspicuous enough to show up on the dark background; it is not the length of the shorter hairs, because these are hidden by the long ones, or even are left behind in the process of pulling the tuft. The grader's "length" is in itself somewhat difficult to define, although it is sufficiently well understood for ordinary working purposes of comparison.

Various methods have been tried in order to bring greater precision into these definitions. In 1863, Mr. C. O'Neill measured a few dozen cotton hairs one by one, and published the data obtained, which have been frequently quoted. Other similar sets of determinations have since been made, but the difficulty inherent in all these methods is that of sampling; it is extraordinarily hard to ensure that the hairs removed for measurement are free from even a moderately high "sampling error"; the advantages of these methods, apart from their sampling error, would be the provision of data as to the percentage of short fibre in the sample, which is a very important factor in predicting the waste which will be made during the spinning process, and at the same time is one which even the most expert grader cannot be completely trusted to assess correctly.

There is an alternative way of measuring length of staple, which practically disregards the waste component, and being effected upon the seed-cotton is therefore useless to the users of the ginned lint. It began with the practice in America of combing out the lint hairs on either side of the seed in the form of two wings, and measuring the length of these two wings.

When the author began his study of cotton, it seemed self-evident that this was a bad way of doing a good thing, for if the hairs were combed differently, so that they formed a halo round the seed with each hair lying approximately along a radius of the halo, and with the longitudinal axis of the seed lying in the plane of the halo (R.C. Pl. V), then the cotton which produced a circular halo with the seed in the centre was obviously more uniform than that which gave an eccentric halo, so that the method provided some indication of regularity of staple.

Apart from this, however, and confining our attention to the mean maximum width of the halo, commonly attained at the butt of the seed, it was found that this could be measured to within a millimetre, and, as data accumulated, we found further that by so doing we had obtained an unexpectedly precise method of lint measurement. The probable error of the measurement made in this way on so few as seven seeds, taken at random from any one plant,

was no greater than the error of measurement from two dozen single-lint hairs even without considering the sampling error of the latter; the adoption of this method alone enabled twenty plants to be studied for every one which could have been studied by the old method, and it is now in general use.

The limitation to the method was its inapplicability to ginned lint, and hence to all consumers' problems, while a further limitation resided in the fact that it gave a numerical statement of the mean maximum length only, and not of the frequency distribution of short hairs in the sample. This latter could only be assessed conveniently by eye-judgment. Consequently, some method was most obviously needed which would handle ginned lint; would handle it in sufficient quantity to blot out the sampling error; would determine, not only the mean maximum length, but also the distribution of lengths of all kinds; and, equally important, would do all these operations quickly.

This method is now available through our invention of a comparatively simple mechanical arrangement which can be worked up to various degrees of operative complexity for the sake of making the mechanism automatic; a provisional patent has been obtained, and one form of it is shown to-day, by the courtesy of my Directors in the Fine Cotton Spinners' Association.

This Length-Sorting Machine consists primarily of a pair of revolving rollers which, as they revolve, are traversed, or translated bodily, along a path at right angles to their axes of rotation. The cotton to be examined is first run through ordinary drafting mechanism, so as to cause the hairs to lie parallel and straight, and this "sliver" is presented to the rollers at the beginning of a traverse until they have seized a millimetre or so of the front ends of the foremost hairs. The sliver is then drawn away, leaving in the nip of the rollers a tuft of hairs which are all held by their front ends.

The rollers continue to revolve, and obviously the first hairs to be delivered from them on the other side will be the shortest hairs, while the longest hairs (since all started with their front ends level) will be the last to escape. But since this feeding action of the rollers is combined with, and positively geared to, the motion which causes the traverse, it follows that the short hairs will escape on to a suitable collecting device at the beginning of the traverse, the long ones at its completion, and intermediate lengths at intermediate points. Thus the cotton is fractionated by a continuous cycle of operations, repeated as many times as is convenient, not merely into separate parcels of hairs, but into a graduated series which may be sub-divided to any degree desired.

Simpler forms of this machine would seem to offer possibilities of useful application in all places where experimental cotton-growing is being carried out. At any rate, we now possess a technique by which we can take a sample of raw cotton, make it into a sliver, treat that sliver for two minutes only in an automatic machine, weigh the graduated produce of the machine's activity, and, at the end of half an hour can plot frequency curves of a reasonable and measurable degree of precision, showing the variation of length of staple within a sample.

Frequency curves showing some environmental variations in this respect, by the four pure strains previously described when grown at different times and places in Egypt and the Sudan, illustrate very well the differences which can exist between different cottons both as regards heredity and environment. It is particularly interesting to note the uniformity of the lint of No. 111, which was the only one of the four strains deliberately chosen for likely agricultural virtues; these virtues included an extremely high percentage of lint per unit weight of seed cotton, a boll which opened nicely, an ability to produce bolls in pairs instead of singly, and an arrangement of lint on the seed which, when combed out, gave an ideal form of circular halo surrounding the seed almost equally in all directions. The effect of this last characteristic is clearly shown in the form of the curve for No. 77, which was noted on the very first seed ever handled (5) as being defective in this respect.*

The Root and the Water-table.

The period from 1895 to 1899 has been described as being the "high-water mark of Egyptian cotton-growing." The area under cultivation with cotton was about 1·1 millions of acres, and the yield per acre was about 540 lb. of lint. Since that period, the area under cultivation has risen to about 1·7 millions of acres (the maximum before the war); but the total increase in quantity of cotton produced by this great increase in the amount of land, labour and water devoted to the crop has been trivial.

* The existence of a mechanism for sorting wool, invented by Herr Schlumberger, came to the knowledge of the author recently through the courtesy of the Bradford Conditioning House's manager, just two years after the first inception of the present machine, and one year after it came into routine use. The Schlumberger instrument, while accurate and useful, is intermittent and non-automatic, and does not employ the traversing roller.

The total quantity of cotton produced by Egypt at the present time stands to the amount produced twenty years ago in the ratio of 6·5 to 6·0; it follows that the effort involved in raising the cotton area by 600,000 acres has given a very small benefit if measured in terms of cotton alone.

During the last few years, the issues involved in this remarkable phenomenon of yield-deterioration have been somewhat obscured by the incursion of a new insect pest, the pink boll-worm, which was first seen in Egypt in 1910, caused damage locally on a commercial scale in 1912, and was the cause of very serious loss and damage to the crop in 1913 and afterwards. Prior to 1912, however, there was no question of pink-worm effects, and even since that year it is perfectly clear, as we shall see later, that much of the damage attributed to the worm, definite though this latter is, has really been due to the same causes which had already brought about the yield-deterioration between 1898 and 1912.

On the first page of the first laboratory note-book which the author started in Egypt, is a summary of the position of cotton problems given to him by Mr. G. P. Foaden, during his first morning at the Khedivial Agricultural Society, stating that there seemed to be at that time, namely, the end of 1904, some reason for believing that the yield per acre was steadily diminishing, owing to some unknown cause, and that this diminution was not merely accidental.

Matters were slightly complicated in 1905 by the exceptionally bad attack of the ordinary boll-worm, which had been known in the country since 1876, though its effects had generally been confused with those of fog and cool weather. As this diminution became more obviously a serious matter, numerous explanations were adduced. We need not discuss these here (27), since they have all been shown to be invalid by actual statistical analysis of the facts, although even at the present time these exploded fallacies are frequently reasserted by reactionaries; the extension of cultivation of land which previously had not grown cotton and the use of artificial manures may be cited as examples.

In the spring of 1906 Mr. J. R. Gibson, English Commissioner for the State Domains —who, in collaboration with his chief engineer, M. Audebeau, had been experimenting and observing during the past year on the basis of a working hypothesis which they had constructed —came to the author's laboratory one morning and informed him that there seemed to be good evidence in favour of their novel interpretation, to wit, that the falling-off in yield was due to a rise in the level of the sub-soil water, or water-table, of the country in general, which rise had been brought about by the extension of the irrigation system during the past decade.

For our present purposes we need not go further into this part of the matter (5, 11, 16, 17, 29). The view was decidedly unpopular, since it necessarily involved criticism of what was then, and must necessarily be, the most powerful and important department of the Egyptian Administration.

The death of Mr. Gibson in 1909 was a serious loss to the increasing body of scientists now converted to this view, while a very early flood in the same year brought the average yield obtained (from one of the most promising crops which Egypt had ever seen) down to the catastrophic figure of 324 lb. per acre, and caused the matter to become very serious politics.

Commissions and committees deliberated on the problems, and in at least one case a committee was appointed and never met at all; but the facts discovered year by year, through the activity of a small school of scientific investigators, were too strong to be still obscured by prejudice. Administrative changes took place, and the present Irrigation Department adopts as part of its fundamental tenets the view that a high or rising water-table is bad for the cotton crop.

At the same time, it is doubtful whether, owing to the complication introduced by the pink boll-worm, it is even now recognised how important the water-table is as a factor in determining the yield of the crop. We shall return to this matter later, and it will suffice for the moment to state the problems in biological terms.

The two originators of the water-table hypothesis were irrigation engineers and agriculturists, not biologists, and so it necessarily fell to the author as the only professional student of plant physiology in Egypt at the time, to develop the biological side of the case, which consisted in the study of root-function and of root-asphyxiation. In passing, it may be mentioned for the guidance of those biologists who may find themselves in a similar predicament, in any country or for any crop, that the most difficult aspect of the whole controversy was that scarcely anybody had the glimmerings of an idea that the root was a living thing, that it required oxygen for its respiration, that if its oxygen supply were cut off, as by immersion in stagnant water, it would die, and that if the

root were dead it would no longer carry on its functions. Controversy on such a subject, under these limitations, was rather like endeavouring to carry on a fight with both hands in handcuffs, and there is no doubt that far more rapid progress would have been made if the scientists had stated their case without scientific reserve.

Year by year, and little by little, from 1907 onwards, our knowledge of the function of the root of the cotton plant increased. As it increased, we realised how small was our knowledge of root-function in any plant, beyond the comparatively elementary facts of the text-books, so that to a very great extent we were not simply applying to the cotton plant the general scientific principles involved, but were semi-consciously building up a general scientific knowledge of root-function, worked out on the cotton plant as our material.

Our preliminary results in this study of the root disclosed a structure of unexpectedly large dimensions. The ordinary field crop of Egyptian cotton is planted in such a way that the plants stand together in pairs, each pair separated from the next pair along a ridge by an interval of about 40 centimetres, and each ridge from the adjacent ridge by about 80 centimetres.

We first showed by excavation and hydraulic mining on a small scale with a needle-jet of water, that the root system in soil which possessed a deep water-table (or had possessed a deep water-table until the autumn), could be traced to a depth of more than two metres, while lateral roots threaded their way through the root systems of adjacent plants to similar distances (29).

The next step was a demonstration of the fact that if such excavations were made in the winter, after the water-table had completed its autumnal rise and had fallen again, and provided that this rise had caused the immersion of the lower part of the root system, then those portions which had been covered by the rising water were found to be dead, though the remaining parts of the root were alive and producing an abundant growth of new roots; these latter passed downwards, and were reoccupying the layer of soil which had been invaded and evacuated again by the water (C.P.E. Figs. 30 and 35).

Another line of inquiry, based on the methods we shall describe in the next section, brought to light a remarkable series of phenomena which we termed "Functional Root-Interference."

At a certain stage in the growth of the field of cotton, the root systems of adjacent plants begin to interfere with one another's function; the time at which this interference takes place can be ascertained to within a day or so by the behaviour of the plants; this necessarily depends on the distance apart at which the plants are spaced, and on the geometrical arrangement of that spacing (A.A.Y. I.).

The effects of this interference are of great economic importance, since they lead to restriction in the water-supply of the plant, taking place at the hottest part of the growing season, and so necessitating very careful control of the water-supply given by irrigation, failing which more or less damage to the plants is caused.

One of the most striking things in this connection is the fact that the Egyptian native cultivator has for decades past pursued the custom of crowding his plants very closely on the available area, at the spacing already stated. For this he has been reproached by numerous reformers of excellent intention, who have pointed out that the United States employed far wider spacing, and they asserted that the Fellah was merely greedy, and was trying to get too much crop from his land. However, when we had completed our analysis of this root problem, we had incidentally shown beyond cavil that the native custom exactly balanced the two opposed causes—namely, gain in crop through having more productive plant-units upon a given area, and loss in crop through root interference.

Further than this, while our researches were being concluded, certain investigators in the United States who had spent some time in Egypt, advocated the application of a closer spacing in the States, with such successful agricultural results that the American cotton-growers are rapidly adopting the Egyptian system, and are thereby obtaining 30 per cent. more crop from their area, and an early crop into the bargain, at no extra cost.

Continuing these studies of the influence of environment upon the behaviour of the crop in the field, aided by the increasing detail and precision of our methods for recording not only the movement of the water-table, but also the water-content of soil above the saturated layer, we arrived at further conclusions.

In respect of soil-water proper we were able to show (37) that by August a cotton crop was drawing almost all its water-supply from a depth of a metre below the surface, at a rate of 50 tons per acre per day, whereas practically none was taken from the surface layers (R.C. Fig. 7). With regard to the water-table, we

were able in 1913 to trace most complex inter-relations between the movements of the water-table in different parts of a thirty-acre field, and to show that, so far from being stagnant, the water-table was continually pulsating under the influence of surface waterings and of changes in the levels of canals, at distances varying from a few yards to some miles away (38). Most of these phenomena had already been demonstrated by other workers since the initiation of the water-table controversy, and we merely added a final demonstration. More important, however, was the effect of this water-table in its big autumnal rise, which takes place as a consequence of the rise of the Nile flood, modified by irrigation practice.

In the year 1909, collaborating with our colleague Mr. Hughes, a "Terrace Experiment" was laid out in the hope that we could detect the effect of the water-table as it rose, by immersing on different dates the roots of the plants which grew on the various terraces; at the same time it seemed that this result had not been demonstrated, owing to accidental circumstances, and not until 1914 were we able to show that these 1909 data had concealed a convincing proof of our hypothesis (A.A.Y. III., Figs. 3 and 14). In 1911 the Survey Department's "Strip Experiment," laid out on a long strip of land which possessed a sloping water-table, showed definitely that the yield was directly proportional to the depth of available soil, but again we had to wait until 1914 for sufficient understanding to demonstrate from the data thus obtained that proof had also then been given as to the injurious effect of a rising water-table (A.A.Y. III., Fig. 15).

Subsequent experiments by the Survey Department staff (particularly Messrs. Ferrar, Hughes and Hurst), as well as by the author, together with the continued studies of M. Audebeau, extended our knowledge in various details, so that at the conclusion of the author's contract with the Egyptian Government, convincing proof was available that a rise in water-table amounting merely to an immersion of 20 centimetres of the root system, would produce permanently injurious effects upon the plants above (A.A.Y. III., Fig. 15).

To summarise the results of these root observations, it would seem that the functional root-system of the cotton plant in field crop might almost be likened to a sweep's brush, driving steadily downwards through the soil, and functional, so far as absorption is concerned, only at the lower end. Any interference with this brush is dangerous.

Graphs of Crop Development.

The phenomena of root-function described in the preceding chapter were, in the majority of cases, not observed directly. It is obvious that a root cannot be taken out from a depth of two metres below the surface, examined, replaced, and then expected to resume its behaviour as if nothing had happened. Practically all these phenomena had to be deduced from the behaviour of the stems of the plants above, and in this connection it may be advisable to add that the root-system, although invisible, constitutes exactly one-half of any plant.

The formation of these deductions was only made possible by our possession of an enormous mass of statistical information which had been obtained by means of a system of Plant Observation devised by the author, and can be presented for study in the form of Curves of Plant Development (A.A.Y. I.-III., etc.).

This system was adopted first by our collaborators in the Survey Department, subsequently by workers on cotton in the Sudan, in the Egyptian Ministry of Agriculture, and later in the West Indies; it is now being extended to the study of various other crops, both at home and on the Continent.

Its utility is such that anyone who has been using these graphs habitually for a year feels entirely at a loss when presented with the results of agricultural experiments in the usual form of expression, namely, the total yield produced; inspection of figures for total yield then produces exactly the same effect of irritation as would an attempt to make use of a dictionary from which most of the leaves had been torn.

In the first instance, the method is based on the statistical study of yields from small plots, which was developed by such workers as Wood, Stratton, Hall, Russell, and Udny Yule, and the publication of Wood and Stratton's first paper reached the author at a time when he had already developed, for purposes of research in cotton-breeding, a system of record for the height, daily flowering, and fruiting of individual plants (15). It needed only one step further to combine the two systems, and from this combination to develop a method of really extraordinary precision.

The basic idea underlying this method was to treat the cotton crop as an average plant multiplied many thousandfold.

Equally important with this was the idea of arranging for the records which show the behaviour of this average plant to be as nearly continuous throughout the season as limitations will permit. We avoided most of the limita-

tions by training ordinary Egyptian native labourers to take daily certain simple observations; these consisted mainly in counting the flowers or fruits, under an arrangement whereby the accuracy of the counts made by each plant observer became self-checking. This was, in fact, an early development of the principle of dilution of labour.

The only remaining difficulty was to obtain a true sampling of the plot, field, province, or country occupied by the cotton plants, so that the statistics might truly portray the average plants concerned. To secure this true sampling entails no especial difficulty since, given certain statistical constants determined by past experience, one can at the beginning of the season lay out as many observation groups each of 200 plants in as many places as may be needed to bring the result to any required degree of accuracy.

It may be added that, if this preliminary arrangement is done carelessly or stupidly, so that nominally comparable groups are not comparable, or so that the sample of plants observed is not a true sample, all the rest of the labour and time expended on these observations is wasted; there is some indication that this has been overlooked in certain recent agricultural publications.

During 1912 and 1913, with seven years' experience of the cotton plant in Egypt behind us, with this system of crop observations in full swing in two or three places besides our experiment station at Giza, and with these curves of crop development growing day by day along millimetre-squared paper on the laboratory walls, we gathered in data and conclusions, both of scientific and of practical importance, almost more rapidly than we could assimilate them. Indeed, it took the best part of two years' desk work at Cambridge subsequently to present them in publishable form, and even so the data published only related to environmental effects, the whole of our genetics data since 1911 being still untouched.

The scientific results obtained were largely concerned with root-function, also with the effect of excessive temperatures upon growth (R.C. Fig. 4)—and this alone suggests sufficient laboratory experimental work for several years' occupation—the permeability of protoplasm in relation to temperature (A.A.Y. II.) (since subsequently and independently worked out by Miss Delf), and many other minor points.

More important than any of these, however, was the statistical recognition and analysis of a phenomenon which we designated by the awkward title of "Pre-Determination" (A.A.Y. III.). This phenomenon is a commonplace of biology, in the sense that hyacinth bulbs raised in Holland pre-determine a better show of bloom than those raised in England, and so forth; but we were able, through our accumulated data, to show that it is a factor which ought to be taken into account at every turn in analysing the effects upon the growing plant of the "limiting factors" of the environment, and it is probably no exaggeration to say that the recognition of this factor will markedly accelerate our progress in the study of living plants growing under the conditions of the open field.

Without discussing this law of pre-determination in detail, we may advert to one of its economic consequences, which is this—

That by making appropriate observations at one stage of the life of an average plant (that is to say, of a crop), we can *forecast* what that crop will do at a later stage; the interval between the original observation and the actual manifestation of its sequel may, in the case of cotton, be as much as ten weeks in length (A.A.Y. III., Figs. 10, 11, 17). Thus, at the end of May 1913, the author was able to forecast, quite against accepted opinion at the time, that cotton would probably arrive in Alexandria during September in greater quantities than it had done for many years past (R.C. Fig. 10).

Confining ourselves to the simpler forecasts, based merely on observations of the rate of flowering of the crop, it should be a comparatively easy matter to effect this for the whole of Egypt, or indeed for any other country, by means of a suitable scattering of observation stations throughout the country concerned.

These observing stations would consist of about ten groups of two hundred plants, each chosen at random in the field of some farmer, who was willing that the observer should visit and observe these groups day by day during the season in order to count the flowers as they opened and the bolls as they ripened. With some fifty such stations scattered about Egypt and reporting the statistical results of their observations, either by postcard or by telegraph, every day to the central station, it would then be a simple matter to prepare and issue graphs showing the development of the cotton crop for the whole country and for particular districts, with organisation exactly similar to that of a weather bureau.

We began an attempt to persuade the Egyptian Agricultural Service to create such a system of precision crop reports, in place of the subjective

and uncertain system based on personal estimates universally employed, but without success. Nevertheless, we venture to think it more than probable that some system of this kind, based firstly on statistical methods of sampling, secondly on the observations of the average plant, and, thirdly, presented and circulated in the form of graphs running completely through the season, will, before many years have elapsed, be adopted for the more important agricultural crops in several countries.

There is one development of this method which is extraordinarily interesting, since it enables us to deduce approximately the form of the fruiting curve for the Egyptian cotton crop during seasons preceding the establishment of direct observations, and although the deduced curves have not the same absolute value as those which we hope to see year by year in the future, they are not without interest, especially in connection with the water-table hypothesis. The available data for their deduction are those for the arrival of cotton at Alexandria, which is the place of export for almost every bale of cotton grown in Egypt.

The ginning factories in the interior of Egypt start work as soon as the picking of the crop commences in each year, and they work at high pressure until the ginning is completed; the first lots of cotton ginned in each season are despatched to Alexandria immediately, the later ones may be held up more or less, according to conditions of market price, transport, etc., with the result that an appreciable amount of cotton may still be coming down to Alexandria as late as thirty weeks after the season commences.

The statistics kept by the Alexandria General Produce Association for these arrivals week by week, have been studied by various people, notably Messrs. Craig and Orenstein, and it has been noticed that the date of average arrivals has shifted backwards during the last decade or so—in other words, the bulk of the crop reaches Alexandria sooner than it used to do. We had always been under the impression that the effect of variations of price, transport, and the like had an overwhelming influence on the rates of arrival, but it occurred to the author after leaving Egypt, that it was just possible that the actual rate of ripening of the crop in the field might be a contributory factor in the rate of arrival at Alexandria. This had indeed long been known to be the case in the matter of the first cotton of the season, but since the bolling curve (which represents the daily rate of ripening of the boll) occupies a period of only two months, whereas the arrivals at Alexandria spread over a period of twenty-five weeks or more (*slide unpublished*), it was clear that whatever effect the first curve had upon the second must be tremendously distorted in time (Preliminary Note in A.A.Y. III., p. 206).

However, we proceeded to turn the arrival figures for each year, from 1898 to date, into comparable form: in the first place, we calculated the arrivals for each week in terms of a single acre from the known total acreage of each season so as to eliminate variations in the area cultivated year by year, and then we calculated the five-week means in order to remove small fluctuations due to public holidays, temporary alterations of price, and the like. Having thus obtained a series of smooth and comparable curves, several interesting facts came to light when these were matched against the statistics for change of price, etc.

The first fact was that, with the exception of only three years in the series, the changes of price appeared to be without any marked effect on the general form of the smoothed curve. In the second place, we found that a simple graphic device allowed one to turn these graphs into something not very remotely resembling a bolling curve. This device merely consisted in the compression of the ordinates for successive weeks by a logarithmic scale, in this way compensating for the slowing down of arrivals which takes place each year as the market becomes full of cotton.

For the season 1909–1913 we possessed precise data from a few sites showing what the form of the bolling curve had been for these places, and by 1913 we understood the causes affecting the forms of these curves sufficiently to be able to draw the probable form of the curve for the whole country. Putting the bolling curves for these five years side by side with the arrivals curves as plotted on logarithm paper, it was immediately obvious that all the salient features of these curves—their rise, their maximum, and their fall—were identical in both cases (*slide unpublished*). We then carried our inquiry backward by examining the available agricultural information concerning the general behaviour of the crops in preceding years, graphed these roughly in the form of bolling curves, and found that they also agreed very well with the arrival curves. Since 1915, comparisons have also been made with the crops produced to date, and there seems to be very little doubt that in spite of all the disturbing causes which might be expected to operate on the rate of arrival at Alexandria, the principal determinant for the form of the arrival curve is the *actual rate of ripening of the cotton* in the field, and that in consequence the Alexandria arrivals give us a first approximation to the form of the bolling curves.

Now the importance of this speculation—though indeed it is something more than a mere speculation—need scarcely be emphasised in connection with our interpretation of the falling-off in yield of recent years as being chiefly due to water-logging.

Assuming that the bolling curve of bygone crops has thus been restored to us by the Alexandria data, we find that the maximum height of the curve, which is an index to the chemical and physical fertility of the soil, has been as great in 1910 and 1913 as it was at the "high-water mark" period around 1898 (*slide unpublished*). We find further, that the curve rises no sooner and no later than it used to do in the past, so that the crop is not deteriorating in that respect either; some years are merely

exceptionally early, others late. In these respects the last few years have been exceptionally interesting. These, however, are trivial and comparatively familiar facts in comparison with the way in which the arrival curve is seen to fall off, when its tail-portion has been compressed by the use of logarithmic abscissæ.

If we except the price-effect in 1904 and 1907, it is quite obvious that the curve is cut off in exactly the same way that the bolling curve or flowering curve is cut off by a rise in the water-table, and the date at which this cutting-off begins has been coming steadily earlier since 1898. A line drawn to represent the cutting-off effect, *i.e.* a smoothing of this part of the curve to a straight line, intersects the base line in 1898 at the thirty-eighth week of the season, as against the twenty-sixth week in 1909 and in 1916.

Thus it would appear that all other things are equal to what they were in the past under similar conditions. The crop is not earlier or later, and the land under favourable conditions of summer water attains to nearly as high a rate of production per acre, but the enormous difference is this—

That whereas in 1899 the maximum rate of production was maintained during a period corresponding to eight weeks of arrivals at Alexandria, it is now maintained on the average for a much shorter period, and even (in the case of such years as 1909, 1916, and 1915) is scarcely reached at all before the cutting-off effect, caused by the rise of the water-table, makes its appearance.

This is exactly in accordance with what research since 1906 has shown about the change in the subsoil water conditions of the country. Evidence from various sources, such as well levels, troubles by seepage of water into the walls of subways and cellars, and the like, shows that the water-table of the country as a whole has been raised nearer the surface to the extent of some two metres as compared with its level in the past, in all the "terres perméables" of the country.

During the greater part of the year this does not matter much, but in the old days a high and early flood had to raise the level of the water-table a considerable distance before the water could reach the roots of the plants. Nowadays, the roots of the plants are, as a rule, already in contact with the water-table when the flood comes down (A.A.Y. III.). Consequently identical floods nowadays cut off the bolling curve some two or perhaps three weeks sooner than they did in the past, and the time of rise of the water-table year by year has reflected itself sooner and sooner in the time of falling-off of arrivals at Alexandria.

The words "time of rise of the water-table" are used advisedly, since this is not the same thing altogether as the time of arrival of the flood; although the former is dependent on the latter, it is capable of control to an appreciable extent by the Irrigation Department, and now that the department recognises the importance of so doing, we find such gratifying results as this: That although the 1917 flood was far worse from this point of view than the flood of 1909, its effects were actually delayed two weeks (on the arrival curves) as compared with the effects of 1909. At the same time, this is not the limit of the control which will be exerted when the yield per acre in Egypt has been restored to its old level, as may be seen from the following figures:—The cutting off of the arrival curve for recent crops has taken place seven weeks sooner than in 1898 or 1899, with the consequent dead loss to the country of some 200,000,000 lb. of cotton, worth at present prices, the colossal sum of twenty million pounds per annum.

The critic may ask why we have neglected the effects of the pink boll-worm in our discussion so far, and the answer is that in spite of the ravages of this new pest from 1913 onwards, the water-table effects are still the most conspicuous feature of the arrival curves. The year 1913 is particularly striking, and shows even more damage due to boll-worm than any subsequent year, because its flood was very late, the latest for a century; the cutting off of the curve by the flood is only just visible towards the end of the season, whereas the fall of the curve takes place at a strange angle and in an unusual way, which can only be attributed to the very bad attack of the pink boll-worm. A minor exemplification of the same effect may be seen on examination of the curve for 1905, which was a bad year for the ordinary boll-worm. After 1913 the arrivals of the crop were disturbed by the war and it is scarcely legitimate to discuss them, but they indicate clearly that the pink boll-worm has not again caused anything like the same amount of loss as in 1913; the small crops obtained have been due to water-table effects in the first instance, and the boll-worm has been unfairly saddled with the responsibility for the whole of this loss.

It must not be thought that this new boll-worm is not a serious pest of the Egyptian crop. It is a most important factor in the situation, especially in affecting quality, and it is remarkable that it should have been able to play havoc with the crop as it did in 1913, when it had only lived in Egypt for some four years, but the outstanding thing is the contrast between the arrival curves of 1898 and 1899, and those of the last decade, when read in the light of this new interpretation.

The foresight of Sir Colin Scott Moncreiff, the founder of the Egyptian Irrigation Service, has been fully justified by events; from the outset of his great work he insisted on the equivalence of drainage with irrigation. Under his successors the former function of the service was not developed and studied to the extent Sir Colin had advised, and the reformation now in course of development under Sir Murdoch Macdonald must necessarily take many years' hard work, study, and productive expenditure before the efficiency of Egyptian soil can be, for the deep-rooted summer crops, brought back to the level at which it might conceivably have been maintained during the past twenty years, had systematic experiment and research been recognised in the interim as being an inevitable concomitant to reconstruction of the State.

Conclusion.

Glancing back over the material discussed in this paper, we may note how utterly impossible it is to demarcate applied science from pure science, as is so frequently attempted. We have pointed out in some places how an investigation begun for strictly economic purposes has shown the existence of great gaps in our knowledge of scientific phenomena, which gaps were filled up automatically in order to complete the economic inquiries. Conversely, inquiries begun with a scientific object simply to strengthen the foundations of our knowledge about the cotton plant, have quite unexpectedly produced results of economic significance. In research of this kind there can be no distinction between pure and applied science; it may be called "pure" because its conduct is guided by the professional methods and etiquette of natural science, or it may be called "applied" because whatever subject may be under investigation, the material is provided by a plant which represents economic values. It is really quite immaterial what we call it, for substantially it is in intention and execution strictly scientific work carried out on an economic material.

One other curious feature of these researches is the rich diversity of subjects they include, of which we have only mentioned a few to-day. This is partly due to the fact that the work was done under circumstances which did not permit of relegating particular problems to specialists to any great extent; partly because such researches are continually infringing on all branches of knowledge, their centripetal whirl taking place round a subject which passes through every range of human interest from Egyptology to engineering.
